UNITED NATIONS ECONOMIC COMMISSION FOR EUROPE

ELECTRICITY SYSTEM DEVELOPMENT: A FOCUS ON SMART GRIDS

OVERVIEW OF ACTIVITIES AND PLAYERS IN SMART GRIDS

UNECE

NOTE

ACKNOWLEDGEMENTS

The study has been prepared by Mr. David Elzinga, UNECE in line with one of the activities of the Work Plan of the Group of Experts on Energy Efficiency for 2014-2015.

INTRODUCTION

The purpose of this study is to provide a brief overview of smart grids and its role in the development of electricity systems. This is accomplished by defining smart grids, highlighting the major drivers for deployment, outlining the range of actors that need to be engaged, and a vision for electricity system development.

The paper presents some possible future work that could be carried out by the United Nations Economic Commission for Europe (UNECE) to both engage in the global smart grid dialogue and serve member States.

WHAT ARE SMART GRIDS?

The development of a "smart grid" is an evolutionary process that happens over time, and not in a single step. Often the deployment of smart grid technologies is referred to as "smartening the grid" or "modernizing the electricity system". From a starting point of an existing grid, or a construction of new networks (or extensions of networks), the deployment of smart grid technologies is not a goal in itself – but rather an enabler to the provision of secure, reliable, clean, economic electricity required by end users. There are numerous definitions, e.g., by International Energy Agency (IEA), European Commission (EC), the United States Office of Electricity Delivery & Energy Reliability (USA OE), International Electrotechnical Commission (IEC) and Japan Smart Community Alliance (JSCA), that seek to describe smart grids (Table 1).

Table 1. Selection of Smart Grid definitions

Author	Definition
IEA	A smart grid is an electricity network that uses digital and other advanced technologies to monitor and manage the transport of electricity from all generation sources to meet the varying electricity demands of end-users. Smart grids co-ordinate the needs and capabilities of all generators, grid operators, end-users and electricity market stakeholders to operate all parts of the system as efficiently as possible, minimising costs and environmental impacts while maximising system reliability, resilience and stability. [1]
EC	Smart grids are energy networks that can automatically monitor energy flows and adjust to changes in energy supply and demand accordingly. When coupled with smart metering systems, smart grids reach consumers and suppliers by providing information on real-time consumption. With smart meters, consumers can adapt – in time and volume - their energy usage to different energy prices throughout the day, saving money on their energy bills by consuming more energy in lower price periods. Smart grids can also help to better integrate renewable energy. While the sun doesn't shine all the time and the wind doesn't always blow, combining information on energy demand with weather forecasts can allow grid operators to better plan the integration of renewable energy into the grid and balance their networks. Smart grids also open up the possibility for consumers who produce their own energy to respond to prices and sell excess to the grid. [2]

[1] International Energy Agency Smart Grid Roadmap: https://www.iea.org/publications/freepublications/publication/smartgrids_roadmap.pdf

[2] European Commission: http://ec.europa.eu/energy/en/topics/markets-and-consumers/smart-grids-and-meters

USA OE	"Smart grid" generally refers to a class of technology that people are using to bring utility electricity delivery systems into the 21st century, using computer-based remote control and automation. These systems are made possible by two-way communication technology and computer processing that has been used for decades in other industries. They are beginning to be used on electricity networks, from the power plants and wind farms all the way to the consumers of electricity in homes and businesses. They offer many benefits to utilities and consumers -- mostly seen in big improvements in energy efficiency on the electricity grid and in the energy users' homes and offices.[3]
IEC	The general understanding is that the Smart Grid is the concept of modernizing the electric grid. The Smart Grid comprises everything related to the electric system in between any point of generation and any point of consumption. Through the addition of Smart Grid technologies the grid becomes more flexible, interactive and is able to provide real time feedback. A smart grid is an electricity network that can intelligently integrate the actions of all users connected to it – generators, consumers and those that do both – in order to efficiently deliver sustainable, economic and secure electricity supplies. A smart grid employs innovative products and services together with intelligent monitoring, control, communication, and self-healing technologies to: facilitate the connection and operation of generators of all sizes and technologies; allow consumers to play a part in optimizing the operation of the system; provide consumers with greater information and choice of supply; significantly reduce the environmental impact of the whole electricity supply system; deliver enhanced levels of reliability and security of supply.[4]
JSCA	In the context of Smart Communities, smart grids promote the greater use of renewable and unused energy and local generation of heat energy for local consumption and contribute to the improvement of energy self-sufficiency rates and reduction of CO_2 emissions. Smart grids provide stable power supply and optimize overall grid operations from power generation to the end user.[5]

Definitions can also reflect national or regional electricity system development needs. For example, in China initial emphasis was placed on the "Strong Smart Grid", reflecting technology development and infrastructure needs in transmission networks. In May 2009, the State Grid Corporation of China (SGCC) officially launched the study and construction of the "Strong Smart Grid" system, to be completed by 2020, noting that this has not precluded efforts by China in distribution technologies. The years 2011 to 2015 mark the construction stage, when rollout of Ultra High Voltage links will be accelerated and urban and rural distribution networks built out.[6]

Even with five different definitions presented not all views are reflected, but the above do provide reasonable consistency. The definitions above do not show any glaring errors or incorrect information, but rather different ways of articulating the development of the electricity system. Therefore to summarize the definition of a smart grid the principal smart grid functional characteristics are:

[3] United States Office of Electricity Delivery & Energy Reliability: http://energy.gov/oe/services/technology-development/smart-grid

[4] International Electrotechnical Commission: www.iec.ch/smartgrid/background/explained.htm

[5] Japan Smart Community Alliance: www.smart-japan.org/english/index.html

[6] http://smartgrid.ieee.org/july-2011/99-chinas-approach-to-the-smart-grid

- Self-healing from power disturbance events
- Enabling active participation by consumers in demand response
- Operating resiliently against physical and cyber attack
- Providing power quality for 21st century needs
- Accommodating all generation and storage options
- Enabling new products, services, and markets
- Optimizing assets and operating efficiently

A smart grid uses digital technology to improve reliability, resiliency, flexibility, and efficiency (both economic and energy) of the electric delivery system. The strategy to achieve this vision hinges upon activities that directly address the technical, business, and institutional challenges to realizing a smarter grid.[7]

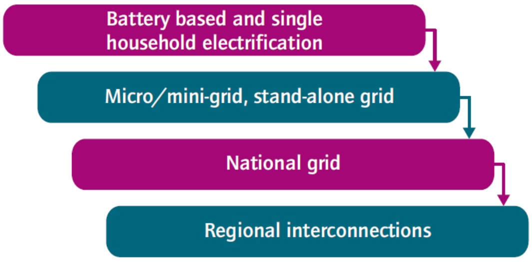
These overall explanations of the smartening of electricity systems can be carried out at a city, national or regional scale, and can also be brought to the level of mini- or micro-grids (Box 1). All electricity systems can be improved or optimised, but it is key to determine what drivers are motivating investments and then to choose investments that can yield the most value for stakeholders.

[7] http://energy.gov/oe/services/technology-development/smart-grid

Box 1. Smart grids in micro-grids and mini-grids

As a means to support access to electricity, smart grids could enable a transition from simple, one-off approaches to electrification (e.g., battery- or solar photovoltaic-based household electrification) to micro- and mini-grids that can later connect to national and regional grids (Figure 1).[8]

Figure 1: Example of access to electricity development pathway



Since the effects of variability (on both supply and demand side) can be felt more acutely due to a smaller base of both generation units and loads, system management to ensure quality and reliably can be quite difficult. Particularly as industrial demands grow in small grids, the task of maintaining adequate power quality becomes a challenge, for example due to spikes associated with the starting current of motor loads[9]. Additionally, many such systems depend on higher priced fuels for fossil based generation (such as oil or diesel), and therefore the use of renewables as well as electricity storage can more easily be deployed in a cost effective manner and at an appropriate scale for currently available technology.

Smart grid components can help cushion such effects and better balance the overall system, again including the integration of demand side management options. Costs of such systems may be further cut through the implementation of direct current (DC) micro-grids, especially when combined with photovoltaic (PV) generation. While losses can be reduced through saving layers of DC/AC power conversion, the more expensive protective devices required for fault management and control, such as coordinated power converters, add complexity and outweigh some of the potential savings.[10]

SMART GRID DEPLOYMENT DRIVERS

Determining which technologies are best suited to deploy in specific electricity systems requires an understanding of the current status of a given system, as well as anticipated future needs. Assuming quality data is collected and available, assessing the status is relatively straightforward, but does require expert assessment. Future needs can be more difficult, where demand is driven not only by the economic development of the country, but also on how energy efficiency, transport systems and industrial activity are planned. The motivating drivers can be crudely categorized across developed and developing economies. Using such labels demonstrates a number of common elements, but also shows varying emphasis (Figure 2).

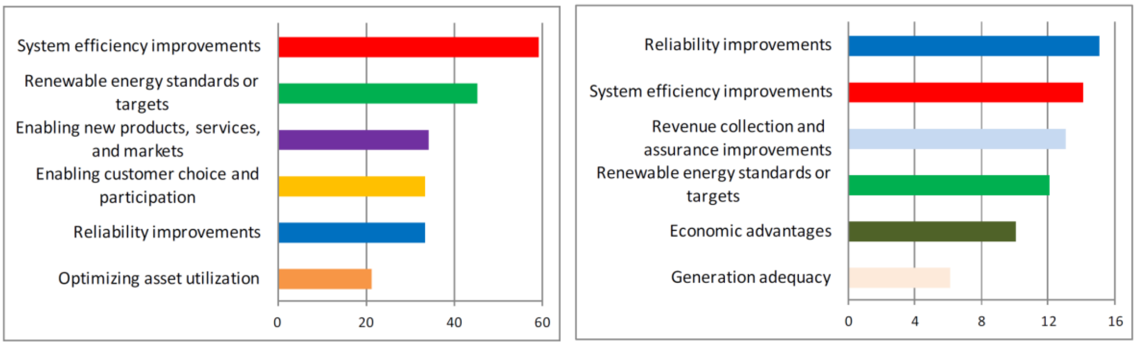
Figure 2. Ranked Smart Grid Technology Motivating Drivers based on country surveys

Developed Economies (left); Developing Economies (right)



Note: the rating system indicates the cumulative rating of survey respondents for each smart grid driver.
Source: Smart Grid drivers and technologies by country, economies and continent. International Smart Grid Action Network (ISGAN), 2014

Common in the top six of each economy type are: system efficiency improvements, reliability improvements and renewable energy standards or targets, but each are placed at different levels of priority. Differences between the two economy types include

- For developed countries:
  - customer choice and participation;
  - new products/services/markets) and optimizing asset utilization.
- For developing countries:
  - economic advantages;
  - revenue collection; and
  - the role of smart grids to support generation adequacy.

Figure 2 yields valuable insights, but it is important to acknowledge that the drivers are still aggregated greatly across countries represented by survey respondents. Choices for the development of a specific electricity system must be made through an analysis that determines needs based on a long term plan that includes social, economic and environmental factors in the given city, region or country. Additionally to what technologies are deployed, it is important to determine which technologies should be deployed as a cluster and in what order in order to get the most benefit for a given investment in the shortest amount of time.

SMART GRID TECHNOLOGIES

There is a very broad range of smart grids technologies. Some of those are commonly applied in many systems today (e.g., smart meters, SCADA and FACTS) and some are still in development or early deployment stages (e.g., PMU, and V2G technologies). Some of the technologies are specific to electricity systems, some cross over into other energy systems and others still are common information and communication technology (ICT) (Table 2).

Transmission systems are typically "smarter" today compared to distribution systems. This is mainly due to the typical scale of transmission systems relative to the respective number of nodes that are managed. Currently transmission systems make up only about 10% of total network length[11], connecting few, but large customers or generators or interconnecting regional electricity systems. An additional reason for the smartness of transmission systems is that the operators at the transmission level typically have been given the responsibility to ensure reliable operation of the entire electricity system. In order to fulfil this task, adequate management technologies must be deployed on the system.

Comparatively distribution networks make up about 90% of total electricity system network length and a very large share (based on the number of connections) of electrical demand and smaller scale generation (both renewable and conventional generation) is connected to distribution networks.[12] In the planning for distribution networks customer demand is often estimated based on historical trends. Distribution electricity infrastructure is typically dimensioned to ensure high levels of reliability under the worst case scenarios – often referred to as "fit and forget[13]". While these approaches have often resulted in high levels of reliability in many countries, existing systems may be over-designed or may not be fit for increased demand (e.g., high penetrations of electric vehicle charging infrastructure in urban centers) or impacts of increased distributed generation deployments (e.g., reverse flows from high penetrations of PV generation in rural networks).

Table 2. Smart Grid Technologies

Technology area	***Hardware***	***Systems and software***	***Network deployment***
Wide area monitoring and control	Phasor measurement units (PMU) and other sensor equipment	Supervisory control and data acquisition (SCADA), wide-area monitoring systems (WAMS), wide-area adaptive protection, control and automation (WAAPCA) and wide-area situational awareness (WASA)	Transmission
Information and communication technology integration	Communication equipment (power line carrier, WiMAX, LTE, RF mesh network, cellular), routers, relays, switches gateway, computers (servers)	Enterprise resource planning soft-ware, customer information system	Transmission and distribution
Renewable, distributed and conventional generation integration	Power conditioning equipment for bulk power and grid support, communication and control hardware for generation and enabling storage technology	Energy management system (EMS), Distribution management system (DMS), Supervisory control and data acquisition system (SCADA), geographic Information system (GIS)	Transmission and distribution

[11] Global Transmission and Distribution Report 2010. ABS Energy Research, 2010.
[12] Smart Grids for Distribution Networks: How to Guide. IEA, 2015
[13] "Fit and forget" refers to the typical approach used to plan and build distribution systems. In this approach distribution systems are dimensioned based on learned (historical) demand patterns, after which they are not regularly monitored to determine whether they are either under- or over-designed. Fit and forget approaches make it difficult to anticipate or manage impacts from generation or demand that diverge substantially from historical patterns.

Transmission enhancement	Superconductors, Flexible alternating current transmission system (FACTS), High-voltage direct current transmission system (HVDC)	Network stability analysis, automatic recovery systems	Transmission
Distribution grid management	Automated re-closers, switches and capacitors, remote-controlled distributed generation and storage, transformer sensors, wire and cable sensors	GIS, DMS, outage management system (OMS), workforce management system (WMS)	Distribution
Advanced metering infrastructure	Smart meter, in-home displays, servers, relays	Meter data management system (MDMS)	Distribution and (transmission)
Electric transportation charging	Charging infrastructure, batteries, inverters	Energy billing, smart charging grid-to vehicle (G2V) and discharging vehicle to-grid (V2G) methodologies	Distribution
Customer-side systems	Smart appliances, routers, in-home display, building automation systems, thermal accumulators, smart thermostat	Energy dashboards, energy management systems, energy applications for smart phones and tablets	Distribution and (transmission)

Note: Where transmission is noted in parentheses, it indicates that the given technology plays a minor role in transmission systems. Information and communication technologies are increasingly found in Transmission and Distribution (T&D) networks and tend to cross all technology areas.
Source: Adapted from Energy Technology Perspectives. IEA, 2012

Smart grids can be a significant tool used to optimize electricity systems by monitoring and managing electricity flows from generation to demand, but it is essential to understand the breadth of technologies across the entire electricity system.

Telecommunications – the heart of the Smart Grid

All smart grid strategies and visions are founded upon the availability of telecommunications network capability. Whether the smart grid objectives are focused upon local, regional or national objectives the majority of Smart Grid applications will rely upon the availability of a telecommunications network for interconnection of the particular generation source, network sensor or smart meter into the power utilities operational processes.

Telecommunications have always played an important role in the management of the power distribution utility operations. Until the advent of the smart grid however this has only been required to deliver connectivity for back office systems and the remote monitoring of high-voltage interconnections with the transmission grid. The need for dynamic monitoring and control was unnecessary, as power flowed in a single direction, primarily from a small numbers of centralized generation plants. Distribution networks could therefore be managed on the basis of predictive grid performance profiles built and validated over many decades of operation.

The demands of climate change and the 21st century information based society however now requires the development of a smart grid which is founded upon communications networks that can deliver centralized real time monitoring and control, eventually across the entire power distribution domain.

It is therefore critical that policy and regulation authorities promote the ability for power utilities to invest in efficient and economic telecommunications systems as the foundation of any smart grid strategy. In addition, a coordinated approach to regional and national infrastructure planning (including transport, gas, water, etc.) can deliver significant economic benefits to support the considerable cost involved in creating an interactive smart grid. The rapid advances in telecommunications technology development in recent years now offer a range of solutions that can be employed to deliver the smart grid. Relevant policy and standards can play an important role in delivering tested and approved product and systems designs that can be adopted effectively by Government and utility purchasing authorities.

As smart grid solutions are deployed across the power delivery value chain, there will be a rapid increase in the points of interconnection with other information networks. As a result the potential threat of cyber-attack to these critical power management systems will build exponentially. It is therefore critical that these policy and standards bodies also ensure that cyber security is mandated as a central and essential element of any smart grid design and operation.

Standards

Within each industry, there are groups of experts who come together to discuss, develop, and update standards. These groups are called standards development organizations (SDOs) or standards-setting organizations (SSOs). For the smart grid, there are over 25 SDOs and SSOs involved in updating current standards and developing new standards. These include, for example, International Electrotechnical Commission (IEC), Institute of Electrical and Electronics Engineers (IEEE), Internet Engineering Task Force (IETF), International Organization for Standardization (ISO), International Telecommunication Union (ITU), North American Energy Standards Board (NAESB), National Electrical Manufacturers Association (NEMA), Society of Automotive Engineers (SAE), and many more.[14] Due to the complexity, number and scale of the systems and devices involved in a smarter grid, interoperability between the various systems is key to successful implementation. Research can address interoperability issues while furthering innovation in grid modernization efforts.[15] One of the key organizations carrying out this effort on an international basis is the Smart Grid Interoperability Panel (SGIP). SGIP brings together over 20 industry segments related to smart technologies and deployment and performs a broad range of work to catalogue standards, develop case studies for technology deployment and provide expert advice on testing and certification aspects.

GLOBAL SMART GRID ORGANIZATIONS

There are a wide range of organizations around the world that are doing work in the area of smart grids, offering technical and policy advice. Some of these organizations are specifically focused on smart grids and others have smart grids as only a subset of a much broader range of activities. Table 3 is meant to provide a list of the organizations making a substantive contribution to global efforts on smart grids, but is not meant to be an all-inclusive list on a global basis.

Reliable and Sustainable Power Grids	GO-15	17 Global Power Grid Operators	Utility	Policy
Union of the Electricity Industry	EURELECTRIC	30 European electricity associations	Utility and Industry association	Policy
21st Century Power Partnership	21 CPP	8 member countries + private sector	Research institute and government	Technology and Policy
Global Sustainable Electricity Partnership	GSEP	12 of the world's largest electricity companies	Utility	Policy and project deployment
The Institute of Electrical and Electronics Engineers	IEEE	395,000 members in 160 countries	Engineering	Research, Policy and Standards

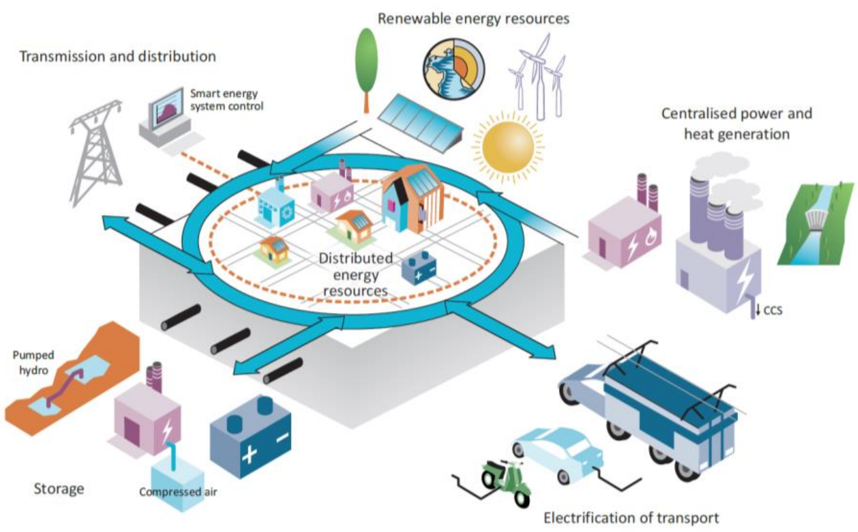
VISION FOR FUTURE ELECTRICITY SYSTEMS

The progress towards an overall smart grid vision can best be articulated by a vision of the electricity system of the future. Today's electricity system is largely defined by large scale generation that produces power which flows in one direction to end users. The electricity system of the future will be defined by the services that electricity can provide, with bi-directional flow of power and information so that generation, distribution and end-users produce or use power while at the same time provide services that can support the operation of the grid (Figure 3). The integrated electricity system of the future can provide electricity in a more efficient manner, demonstrating net savings through better asset utilization of the grid, generation and end-use resources. Smart grid

[16] Non-exhaustive list of multi-national organizations with substantive smart grid activities; a more fulsome description of organizations with exclusive smart grid mandates are included in Annex.
[17] Primary participation, but not exclusive
[18] ISGAN and GSGF have signed a memorandum of understanding to work together on common goals.

technologies will play a huge role in this, but technology on its own will not be sufficient, rather supportive policy and regulation will be essential. By enabling smart grid technology deployment through flexible policy and regulations the learning process needed to find technically and culturally relevant solutions in countries around the world can be accelerated.

Figure 3. An interconnected and integrated electricity system of the future



Source: Energy Technology Perspectives. IEA, 2014

Key Message: A sustainable electricity system is a smarter, multidirectional and integrated energy system that requires long-term planning for services delivery

The role of smart grid technologies and the smartening of the grid (or grid modernization) are important for all electricity systems globally. Well established and reliable grids can still improve operations and maintenance in incremental steps to maximize asset utilization. Alternatively, many existing grids in developing and developed countries today have not been well maintained or upgraded, and therefore significant investments are needed. Smart grid technologies can be used to better assess the most urgent needs as well as adapt to changing social and technical requirements, leveraging these opportunities for more optimum electricity system development (such as demand response and electric vehicles). Well planned approaches that consider long-term investment horizons and best in class technologies can ensure that investments today do not become the burdens of tomorrow.

Building new infrastructure to provide electricity service to new consumers can offer different challenges, but in some ways can be easier. In provided access to electricity, designs are not encumbered by existing infrastructure and therefore can build systems tailored to meet short-term and anticipated long-term needs.

One important aspect to consider is that while there is adequate opportunity to learn from other countries and regions (for both modernization and new build opportunities), there will often be technical, social or regulatory aspects that will require specific solutions. This means that it will be essential to understand the country or region specific context in order to create plans that are best suited.

POTENTIAL CONCRETE NEXT STEPS FOR UNECE

There are several opportunities for UNECE to provide meaningful input into the global smart grid dialogue, as well as provide policy advice and guidance to UNECE member States. Several proposed actions could be considered by various UNECE Committee on Sustainable Energy Groups of Experts, to be carried out individually or jointly:

- Survey of member countries (especially focusing on countries not well served by existing smart grid organizations) to determine existing plans for electricity system development and smart grid efforts.
    - Result: Report on findings to assist in the development of a targeted work plan in support of a member State electricity system development.
- Analysis of electricity generation and demand in UNECE sub-regions to determine existing trends, as well as data gaps.
    - Result: Synthesis report and fact sheets on all member States outlining current trends. Regional aggregations could also be used to assess opportunities to establish cross-border electricity system relationships.
- Outline cross-cutting linkages across UNECE Committee on Sustainable Energy Groups of Experts (Gas, Renewable Energy, Cleaner Electricity Production from Fossil Fuels, and Energy Efficiency) to map out more holistic approach to electricity system analysis for member States.
    - Result: Proposed electricity focused work that could be placed under one of the Group of Experts or the creation of a cross-sectoral task force focused on electricity system development.
- Membership of UNECE Secretariat in the International Smart Grid Action Network (ISGAN) under formal or observer terms. This would offer representation of the larger UNECE membership (especially Eastern Europe, the Caucasus, and Central Asia), alongside UNECE member States that are currently members.
    - Result: Access to a significant knowledge base from and direct links to existing ISGAN members. Input from ISGAN members into UNECE member States' electricity system planning processes.
- Development of a forward-looking analysis for part of the UNECE membership that does not currently have adequate resources to develop this on its own. Such efforts could be done in collaboration with international organizations such as the IEA, European Commission, Asian Development Bank (ADB) or others.
    - Result: Informative analysis that could be used to develop energy systems in ways that could meet sustainability goals, especially targeted on electricity systems.

The above options have varying resource requirements and timeframes. Some options could be used as scoping elements for longer term and larger initiatives.

ANNEX: Short description of Smart Grid organizations

International Smart Grid Action Network

ISGAN's vision is to accelerate progress on key aspects of smart grid policy, technology, and related standards through voluntary participation by governments in specific projects and programs. ISGAN will facilitate dynamic knowledge sharing, technical assistance, peer review and, where appropriate, project coordination among participants. ISGAN activities center on those aspects of the smart grid where governments have regulatory authority, expertise, convening power, or other leverage, focusing on five principal areas:

1. Policy standards and regulation
2. Finance and business models
3. Technology system development
4. Workforce skills and knowledge
5. Users and consumers engagement

ISGAN facilitates dynamic knowledge sharing, technical assistance, and project coordination, where appropriate. ISGAN participants report periodically on progress and projects to the Ministers of the Clean Energy Ministerial, in addition to satisfying all IEA Implementing Agreement reporting requirements. Membership in ISGAN is voluntary, and currently includes Australia, Austria, Belgium, Canada, China, Denmark, the European Commission, Finland, France, Germany, India, Ireland, Italy, Japan, Korea, Mexico, the Netherlands, Norway, the Russian Federation, Singapore, South Africa, Spain, Sweden, Switzerland and the United States.

ISGAN has also published a number of case studies on smart grid projects that can be found at: http://www.iea-isgan.org/index.php?r=home&c=5/378

Source: www.iea-isgan.org

Global Smart Grid Federation

Over the past several years, various countries have initiated projects and programmes to explore the potential of the new generation of information- and communication-based technologies emerging across the power sector. As these efforts matured, formal public-private initiatives were formed. The first, in 2003, was the GridWise Alliance in the United States. It was followed by similar initiatives in the European Union, South Korea, Japan, Australia, Canada, India, and Ireland. Many other countries are in the formative stages of their own initiatives.

The Global Smart Grid Federation was formed to:

- Facilitate the collaboration of national and international smart grid non-governmental organizations and governmental organizations from around the world to conduct and foster research in the application of smart grid technologies
- Support rapid implementation of smart grid technologies by establishing itself as the global center for competency on smart grid technologies and policy issues
- Foster the international exchange of ideas and best practices on energy issues, including reliability, efficiency, security, and climate change

- Create avenues for dialogue and cooperation between the public and private sectors in countries around the world on issues relating to the deployment of smart grid technologies.

Each member organization has a seat on the board of directors, which directs all activities of the Global Smart Grid Federation. The bylaws of the organization will be jointly developed and endorsed by the charter members.

Source: www.globalsmartgridfederation.org

European distribution system operators (EDSO) for Smart Grids

EDSO for Smart Grids gathers leading European distribution system operators (DSOs) for electricity, cooperating to bring smart grids from vision to reality in Europe and is focused on guiding European Union RD&D, policy and member state regulation to support this development. EDSO for Smart Grids represents 30 leading DSOs operating in over 17 countries of the European Union and covering up to 70% of European customers.

EDSO is directly involved in a number of EU-funded smart grid projects, under the EU's 7th Framework Programme (FP7), its successor for the period 2014-2020, Horizon 2020, as well as the Intelligent Energy Europe (IEE) programme.

These projects, evolvDSO, GRID+Storage, and FLEXICIENCY involve exercises in:

- Addressing evolving DSO roles
- Demonstrations (real-life and simulations)
- RD&D mapping and prioritization
- Knowledge-sharing from projects
- Developing and testing market platform for flexibility services
