## **Abstract**

The selection of items for continuous price monitoring in geographical areas/regions is premised on the item's importance in each consumption basket derived from proportion of household consumption expenditure for the Elementary Aggregates (EA) of items and the availability of items in the markets. Basing on household consumption expenditure data of Uganda, some prominent items in the consumption basket whose prices are permanently missing in the regional markets where they consumed are, however, priced using prices from other regions mainly Capital City. This is likely to bring in an element of bias as the prices being used are from other markets. The alternative would be to exclude such items from the regional basket and include their weights in the region where prices are observed, leading to a variation in consumer price index (CPI) for the regions in question although the national CPI would remain unchanged. The extent of the change in the regional CPI is the issue this paper seeks to investigate by focusing on used vehicles that households from other regions purchase from Kampala Capital City. The results from this investigation will help price statisticians in understanding the implication of the pricing options they employ in compiling regional CPIs.

The study shows that the weights for each of the 10 consumption baskets changed. In addition, the weights within each of the consumption basket changed more especially the Transport Division weights. The extreme case was registered on the Mbarara basket whose transport division changed sharply.

Results show that the All Items CPI and the All Items Annual Inflation for each of the consumption baskets for both the published and those under study were not much different and in some cases exactly the same at the significance level of dissemination.

The CPI for the Transport Division for the Mbarara basket and the corresponding annual Inflation for both the published and those under study are significantly different. This is due to a relatively very big expenditure on second hand vehicles by the households of Mbarara sub-region that was reallocated. This implies that given the increasing demand data at disaggregated level more especially at lower levels of local administration, the choice taken to compile the CPI leads to different results and wrong choice may be undertaken. Removing expenditure from a sub-region because it cannot be priced should be avoided.

Some countries have established regional economic blocks e.g. East African Community (EAC), Common Market for Eastern and Southern Africa (COMESA), South Africa Development Community (SADC) etc... Those regional blocks do compile the Harmonised Consumer Price Indices (HCPI) and they follow the domestic concept. In order to have meaningful sub-regional indices within a country, I would recommend the domestic concept should be restricted at the national level and the expenditure within the country be allocated to the households within the sub-region they reside. This implies using the domestic concept at the national level and following the national concept at the local level.

The results show the need to ensure that all prices entered for the computation of the CPI are of very high quality since price movements have a much bigger impact on the inflation to be published and disseminated.

**Key words: Elementary aggregate, household consumption expenditure, consumption basket**

# **I. BACKGROUND**

## **1.1 Introduction**

The capital city of Uganda is Kampala while the population of Uganda is 34.6 million as per the 2014 Uganda Population and Housing Census (UPHC) 2014. Uganda compiles and disseminates the national Consumer Price Index (CPI) on a monthly basis. The national CPI is based on two categories of stratification. The first category is the geographical stratification while the second category is the income group stratification. The CPI for the above two categories are compiled and disseminated. The CPI for each geographical area and income groups are used by individuals and organizations as basis for their decision making policy. The main objective of the stratification is to improve the quality of the National CPI. Uganda is demarcated into 5 CPI Statistical regions. The regions are Kampala which is the capital city, Central<sup>2</sup>, Northern, Western and Eastern. The Regions are further subdivided into 10 Statistical sub-regions in total. The sub-regions are : Kampala; East Central; Eastern; Central 1; Central 2; South-Western; Mid-Northern; West-Nile; Mid-Western; and North East.

The Uganda national CPI is a weighted average of 10 sub-indices also known as 10 consumption basket indices. The CPI for the 10 consumption baskets are compiled such that all the 5 regions are represented. Consumer prices are collected from the capital city as one of the sub-regions and also from other 7 urban areas that represent the rest of the 9 sub-regions. Thereafter, monthly CPI is compiled for each of the 7 urban areas while the capital city is decomposed into 3 income groups namely Kampala High Income, Kampala Middle Income and Kampala Low Income. Similarly, monthly CPI is compiled for each of these income groups. That is how the ten sub-indices or 10 basket indices are arrived at. The current CPI has 2009/2010 financial year as the index reference periods for price, weight and index.

The major source of information used for the derivation of the CPI weights is the results of the Household Consumption Module of the Uganda National Household Survey (UNHS) IV that was carried out from May 2009 to April 2010. Since the UNHS was not designed purposely for the CPI weights, more additional data sources were used for the compilation of reliable weights. Some of the additional data sources used were the National Accounts data (for the final household consumption) and the results of the 2012 Tourist Expenditure and Motivation Survey (TEMS). A Household budget Mini-Survey was also conducted to collect additional data.

## **1.2 Determination of the 10 CPI consumption baskets**

The 10 consumption baskets are based on the urban household final momentary consumption expenditure on the entire economy. Kampala region where the capital city is located is treated with a unique status thus it is a sub-region of its own. Her household final consumption expenditure was decomposed into 3 CPI consumption baskets based on the income groups: Kampala High Income basket, Kampala Middle Income basket and Kampala Low Income basket. The rest of the 7 baskets

---

<sup>2</sup> Kampala which is the Capital city of Uganda is located in the Central region. However, for the CPI Regions, Central Excludes Kampala since Kampala is also a CPI region

were determined from the remaining 9 sub-regions. The seven sub-regions were selected in such a way that all the remaining 4 regions are represented. One sub-region was selected from the central region while two sub-regions were selected from each of the remaining three regions. The urban household expenditure for each of the selected sub-region became a CPI consumption basket. The urban household expenditure for the remaining two sub-regions, were proportionally distributed to the selected sub-regions that are close geographically. Due to resource constraints, 2 sub-regions could not explicitly be included in the CPI. The criteria for those excluded was one of the sub-region had a much smaller expenditure compared to the rest while the second was close to Kampala where it is assumed that much of its price movements is captured in Kampala. However, with additional resources, geographical expansion will be increased. After the selection of the 7 sub-regions, one urban centre was selected from each of the selected sub-regions. The selected urban was the one with the biggest number of population as par the 2002 Uganda Population and Housing Census.

### **1.3 Determination of Income Groups**

Kampala, which is the capital city, was stratified based on income groups. Based on the household final consumption expenditure as a proxy for the income groups, three income consumption basket groups were categorized as: High Income basket, Middle Income basket and Low Income basket. The Kampala High Income basket is the 10th deciles<sup>3</sup>, i.e. the expenditure of the top 10% households for Kampala sub-region. Kampala sub-region comprises the entire Kampala City Council Authority (KCCA); The Kampala Middle Income basket is the 7th-9th deciles i.e. the expenditure of the top 30% households for the Kampala sub-region removing the top 10% households for the Kampala High Income. The Kampala Low Income basket is the 1st-6th deciles i.e. the expenditure of lowest 60% of the households for Kampala sub-region.

### **1.4 Computation of weights**

After determining both the seven regional baskets and the three income group baskets, household final consumption expenditures for each of the 10 baskets were classified according to COICOP. However, illegal and black-market expenditures such as prostitution and narcotics were excluded; so was life insurance because it is regarded as an investment. Also excluded, for practical reasons, were Games of Chance (Gambling) and Financial Intermediation Services Indirectly Measured (FISIM).

The weights for the Uganda CPI basket were computed in three stages: The first stage was the computation of elementary aggregate weights and higher level aggregate weights within each of the 10 consumption basket; the second stage was the computation of weights for each of the 10 baskets; and the final stage is the computational of national weights for each of the elementary aggregates and higher level aggregate weights.

#### **1.4.1 Elementary Aggregate weights within each consumption basket**

After classifying all household expenditures within the COICOP headings for each of the 10 baskets, the proportion expenditure for each of the Elementary Aggregates (EA) and for each basket was computed and their total sum scaled to 1,000. The cut off point for an EA to be included in the CPI was set at 1 part per 1000. Cases where the proportion expenditure of an EA fell below the threshold, the expenditure for such an EA was proportionally redistributed among the remaining EAs within the same COICOP sub-class or class. In some situations, the expenditure for such an EA was

---

<sup>3</sup> a **decile** is any of the nine values that divide the sorted data into ten equal parts, so that each part represents 1/10 of the sample or population

combined with another EA to form a new EA provided there was homogeneity of products within those EAs.

#### **1.4.2 Higher Level Aggregate Weights for each consumption basket**

Higher level weights are weights above the Elementary Aggregate Level. These were computed as the total sum of weights for those EAs that are classified under that Higher Level Aggregate.

#### **1.4.3 Computation of consumption basket weights**

The second stage was to compute consumption basket (geographical area and population income) weights. The weight for each of the geographical area and population income group was computed as proportional of the geographical area or income group household expenditure to the total expenditure for all the 7 geographical areas and the 3 population income groups.

#### **1.4.4 Computation of National weights**

The final stage was to compute the national weights. These are the combination of weights within the consumption basket together with those between the consumption baskets.

### **1.5 Selection of Locations for Price Collection**

After the determination of the 10 consumption baskets i.e. 3 income population group baskets and 7 geographical area baskets, the next step was to select locations where to collect consumer prices on a regular basis. Uganda disseminates the National CPI, CPI for each of the 3 population income groups and CPI for each of the 7 geographical areas. This implies that consumer prices should be collected from locations and outlets that will reflect a change in prices that is being experienced by the households the CPI is targeting. For the 3 population income groups in Kampala, consumer prices are collected from the locations where each category of the income normally purchases such items. For the 7 geographical areas, due to limited resources, only one urban centre is selected for each of the 7 geographical areas and consumer prices from the selected urban centre are used to compile the CPI for the sub-region. The criteria used for the selection of the urban centre for price collection is based on the numbers of the 2002 population and housing census results. Thus, an urban area within the sub-region with the highest number of population was selected.

### **1.6 Naming of the Geographical Area or Sub-Region**

The name of the selected urban area for price collection as explained in the section above is the name that always referred to for the sub-region or geographical areas.

### **1.7 Selection of items**

After the determination of the EAs, the next step was to select items within each EA for each of the 10 consumption baskets. Four approaches were used to select the list of the items. The first approach was to use the list of items that was available in the previous CPI before the General Rebasing exercise. Here, all items in the previous CPI that were still popular and representative on the market were selected and kept in the revised CPI. The second approach used to select CPI items was to use 2011 ICP list of items. From that ICP list, only representative items were selected and incorporated into the CPI baskets. The third approach was to select a list of items that were found with a significant expenditure as the results of the 2014 Min household budget survey. The fourth approach was to select items from the open market. This is where the required representative items could not be obtained from the above two data sources. In this case, the required representative list of items was selected from various outlets in consultation with the respondents i.e. the business community.

## **1.8 Selection of outlets**

After the selection of items, the next step was the selection of outlets. Three approaches were used to select outlets from which items are priced regularly. The first approach was to use the outlets that were available in the previous CPI. Here, all outlets in the previous CPI that were still popular and representative were kept in the revised CPI. The second approach used to select the outlets was to use the 2011 ICP list of outlets. From the ICP list, only representative outlets were selected from this list and incorporated into the CPI outlets. The third approach was to conduct field visits using field staffs to identify outlet-types and concrete outlets that are representative of the items to be priced. This is where the required representative outlets from which certain items could not be priced using the first two approaches were selected. Non-random (purposive) approach was and is still employed in selecting outlets. For example, outlets that are selected are those most frequented by the households. When an outlet closes permanently, it is replaced with another outlet with similar characteristics and its location should not be far from the one which closed down.

## **1.9 Price Determining Characteristics**

After the selection of items and outlets, the next step was the identification and documentation of price determining characteristics more especially for the newly introduced items. This was done in consultation with the respondents.

## **1.10 Collection of Consumer Prices**

Consumer prices for each of the 10 consumption baskets i.e. 7 geographical areas and 3 population income groups are collected from the 1<sup>st</sup> to the 15<sup>th</sup> day of each month. This implies that any price change after the 15<sup>th</sup> of any particular month is reflected in the CPI of the following month. Consumer prices for most of the CPI items are collected once a month, some twice a month and other are collected more than one month interval. The frequency of collecting prices of any item depends on its volatility. For instance prices for fresh food crops such as fresh vegetables are collected twice a month; rental charges are collected once in a quarter; education charges for pre-primary, primary and secondary schools are collected once in an academic term and the timing of price collection is at the beginning of every academic term. Education charges for tertiary institutions are collected once in an academic semester and timing of price collection is at the beginning of every Semester. The CPI units of measurements for education charges during the computation of the CPI are the academic term and academic semester respectively.

Prices for each basket are collected from the geographical area pertaining that very basket. However, there are cases of items where prices are permanently missing in a geographical area and households of that very area make purchases of those items from another region. Example of such items is the second hand vehicles. The prices for such items are collected from a different region where there are available and thereafter used to compute the index of the sub-regional where prices for such items are permanently missing. In Uganda, CPI items might be available in the selected geographical areas but it is extremely difficult to be priced in some of the areas. Example of such cases is consumer prices for second hand clothes. In this case prices from other geographical areas are used during the compilation of the sub-regional CPI where such prices cannot be collected. Second hand clothes are some of the hard to measure products in the Uganda CPI. Here, the principle of comparing like with like is very difficult to maintain during the CPI compilation. In this case, proxy prices of wholesale prices for the second hand clothing are used.

All the collected prices are validated and any missing prices are imputed before they are used to compute the CPI.

### **1.11 Computation of the CPI**

Computation of the CPI is carried out in three stages: The first stage involved the computation of the Elementary Aggregate Indices for each of the 10 consumption baskets. Elementary aggregate indices for the CPI are calculated using the geometric mean (GM) method, commonly referred to as the Jevons index; the second stage is the computation of the Higher Level Indices for each of the 10 consumption baskets. These are the indices at levels above those of the elementary aggregate indices. They are in hierarchy, starting with sub-class indices, class indices, group indices, division indices and all items index. Higher level indices are calculated as weighted averages of the indices for all the components within that higher level aggregate. The third and final stage is the computation of the National Index. The National indices at all levels are calculated directly as the weighted average of the 7 geographical area indices and the 3 population income group indices i.e. a weighted average of the 10 consumption baskets.

### **1.12 Dissemination of the CPI**

CPI and the corresponding weights are disseminated at the national level and also by geographical area and population income groups. The CPI for any particular month is disseminated to the general public at 11.00am on the last working day of that particular month, through a press conference, electronically specifically on the UBOS website and on e mails for specific data users. In addition, major stakeholders such as Bank of Uganda (Central Bank) and the Ministry of Finance, Planning and Economic Development at the same time when national dissemination of the CPI to the media is taking place.

The disseminated components of the national CPI and their derived inflation rates are: Headline Index which is a combined index for all items of the 10 consumption basket, the corresponding core and non-core indices, service indices, energy, fuel & utilities indices, food crops and related items indices and other goods indices; and indices for the 12 COICOP divisions. Other disseminated components are the All Items indices for each of the 3 population income groups; and the All Items indices for each of the 7 geographical areas. Further analysis is still on-going to categorise the CPI basket between tradable and non-tradable so that the indices of the two categories is added to the disseminated components.

The weights at any level are disseminated at 4 decimal places, index numbers at 2 decimal places while inflation rates at one decimal place. Here given below are the inflation rates disseminated to the general public.

### **1.13 Computation of the derived Statistics**

Most users are interested in statistics that is derived from the computed index numbers which is the inflation rates. The most used inflation numbers are monthly inflation, annual inflation and annual average inflation. All the inflation numbers are disseminated at one decimal place. The above numbers were computed as explained below.

**1.13.1 Monthly Inflation Rates** are calculated as the percentage change between the CPI of the current month and the CPI of the previous month.

**1.13.2 Annual Inflation Rates** are calculated as the percentage change between CPI of the current month and the CPI of the same month but for the previous year.

**1.13.3 Annual Average Inflation Rates** are calculated as the percentage change between the Annual Average CPI for latest 12 consecutive months and the Annual Average CPI for the same 12 consecutive months of the previous 12-month period.

## **2. FINDINGS OF THE STUDY**

### **2.1 Introduction**

The study is on the monthly CPI for the period July 2010 to March 2016. Sections 1.9 – 1.13 above are about collection of consumer prices, computation and dissemination of the CPI. It is clearly indicated that consumer prices for each consumption CPI basket are collected from a particular geographical area and used to compute a sub-regional CPI for that particular areas, which thereafter are combined together to get the national CPI. However, there are special cases where households do consume certain products but households buy such products from a different geographical area. This study has singled out one set of items namely second hand vehicles. In Uganda, household net final consumption of second hand vehicles in all the regions is significant and keeps on increasing. However, the only market from which households do buy such products and where price collection could be carried out on regular basis and comply with the principal of compare like-with-like is Kampala.

The study investigated the impact on the published CPI whereby instead of using consumer prices for second hand vehicles from Kampala to compute the CPI for other regions where such prices do not exist, the household net final expenditure on second hand vehicles for other regions should be allocated to Kampala and find out the impact of the published CPI for each of the published 10 consumption baskets i.e. 3 population income group indices and 7 geographical area indices. The study looked at three dimensions as follows: Weights, Index numbers and Inflation rates.

### **2.1 Consumption Basket Weights and Weights for Transport Division**

The consumption expenditure for second hand vehicles for the 7 geographical areas was proportionally allocated to the 3 Kampala population groups. This had an impact on the weights as follows: i) the weight for each of the 10 consumption basket changed and ii) the weights for each of the elementary aggregate within each of the 10 consumption baskets changed. As a result, the entire national weights system changed more especially the Transport Division.

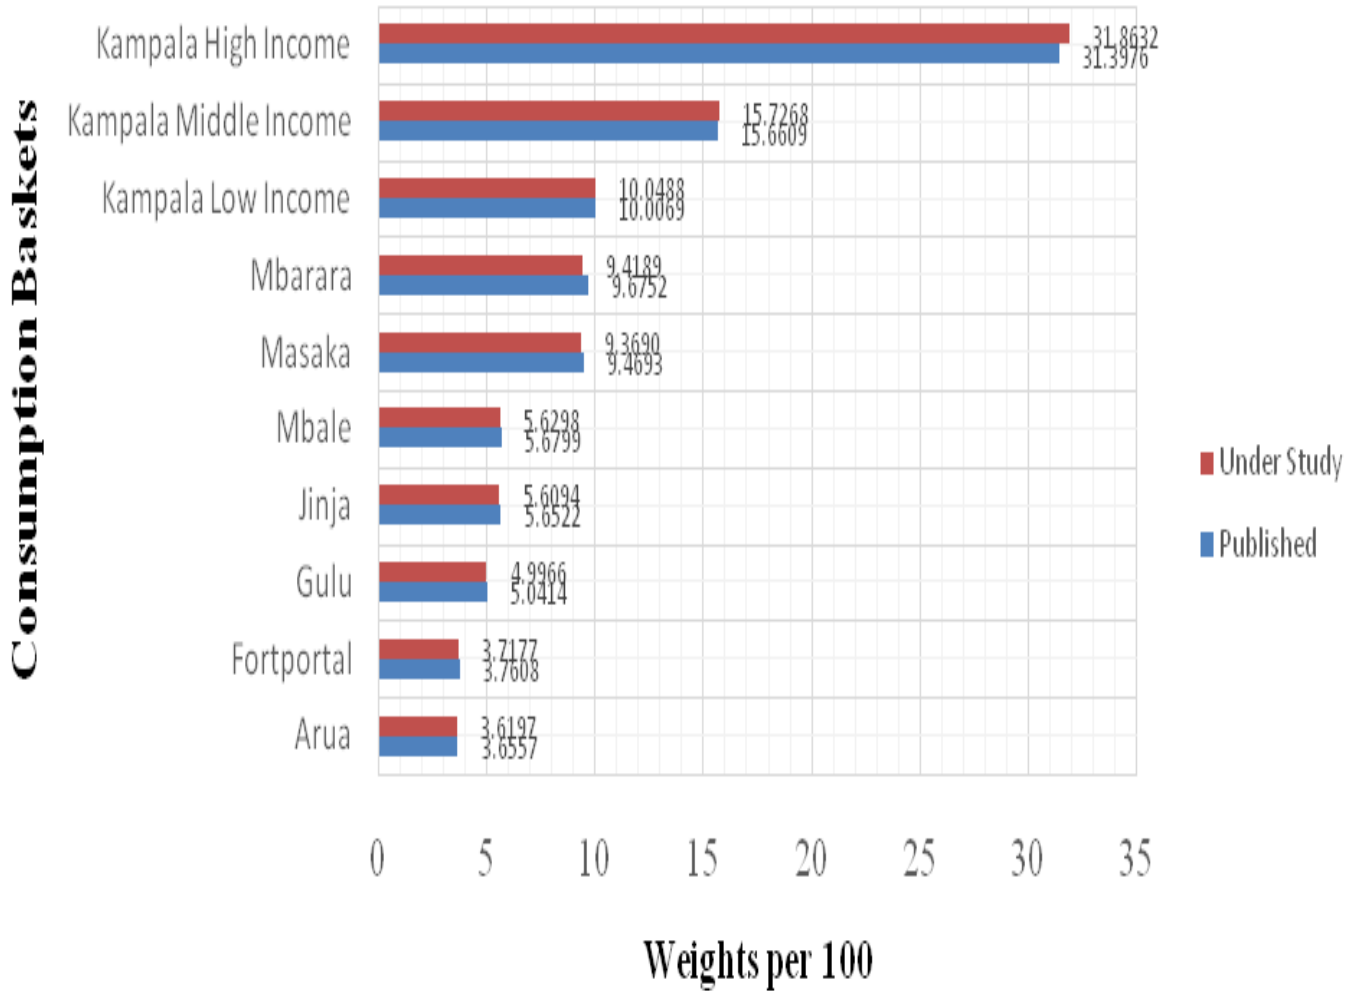

#### **2.1.1 Consumption baskets weights**

The consumption baskets<sup>4</sup> are: Kampala High Income, Kampala Middle Income, Kampala Low Income, Mbarara, Masaka, Mbale, Jinja, Gulu, Fort Portal and Arua. The consumption basket with the biggest increase in weight is Kampala High Income while that with biggest drop is Mabarara basket. The weight for the Kampala High Income basket increased from 31.397 parts per 100 to 31.8632 parts per 100 which is an increase of 1.5 percent. On the other hand, the weight for the Mbarara basket dropped from 9.6752 parts per 100 to 9.4189 parts per 100 which is a drop of 2.6 percent. Graph 1 below gives changes in weights for each of the 10 consumption baskets. More details about the changes in weights for each of the 10 baskets is attached in Table 1.

---

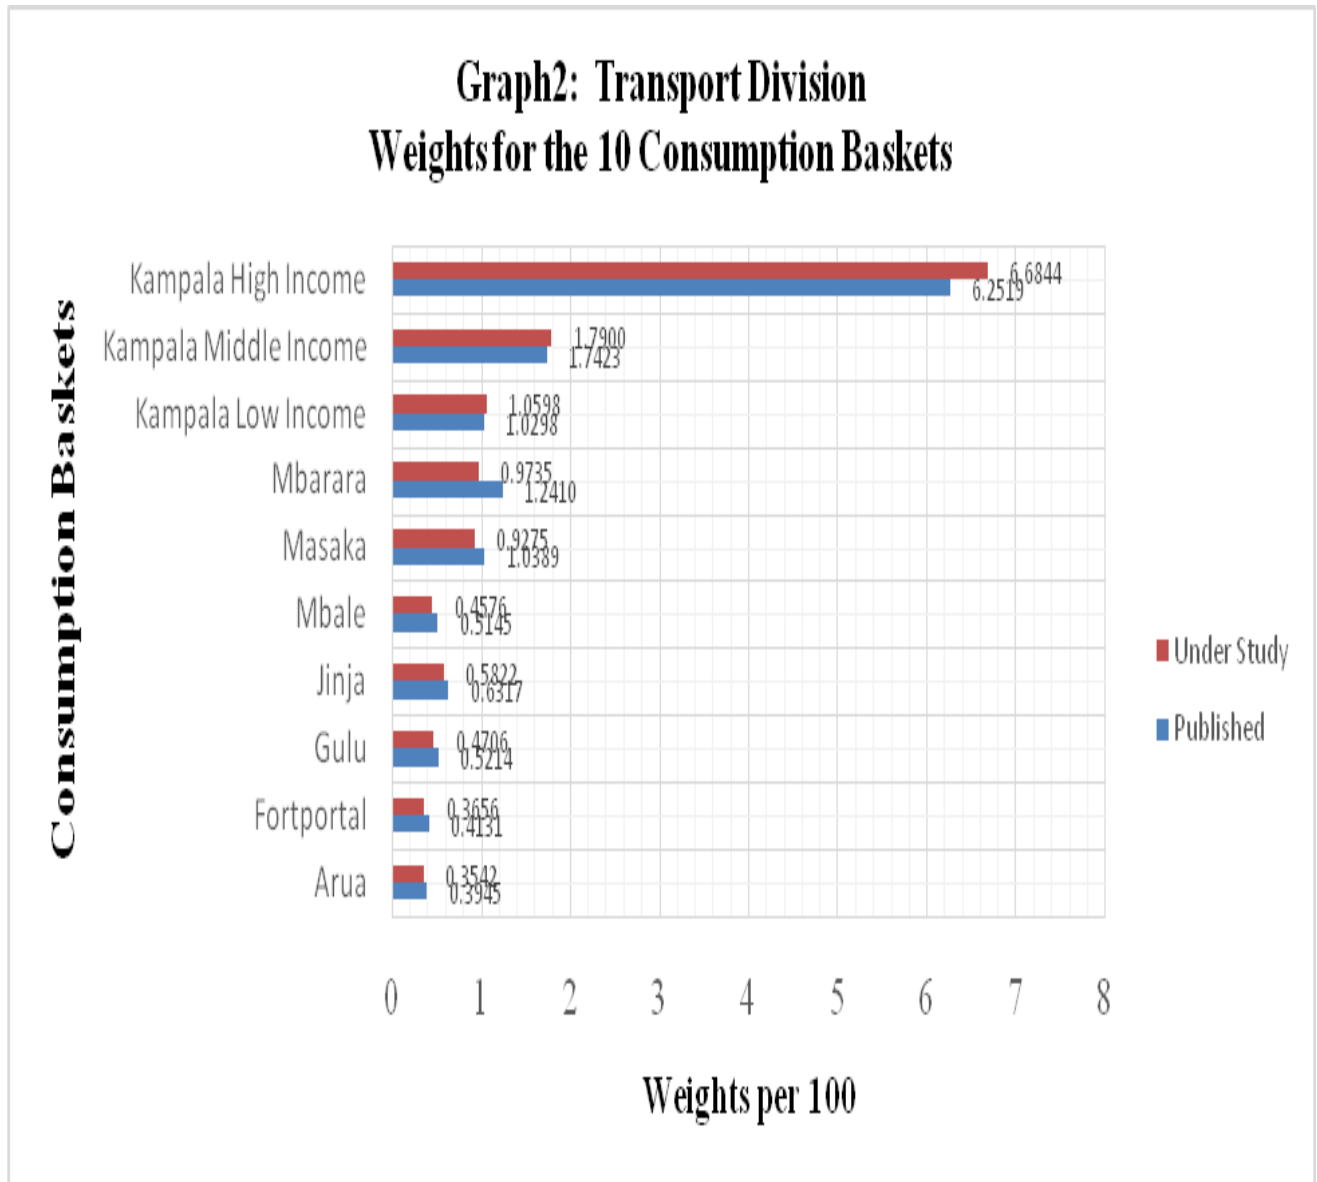

<sup>4</sup> Representation as in section 1.6

**Graph1: All Items CPI Weights for the 10 Consumption Baskets**

**2.1.2 Weights for the Transport Division.**

The weights for the Transport Division changed substantially within the 8 consumption baskets where the Kampala Low Income and Kampala Middle Income baskets registered minimal changes in the transport division. The weight for the Transport Division for Mbarara dropped drastically by 21.6 percent, followed by that of Fort Portal which dropped by 11.56 percent as shown in graph 2 below. More details about the changes are shown in tables 2.

## **2.2. Annual Inflation Rates for the “All Items” Baskets and the Transport Division**

A comparison for each of the 10 consumption baskets was made at the “All Items” levels between the published CPI and the CPI under study for each of the 10 consumption baskets. The study went deeper to look at the annual inflation rates for the transport divisions for both the published and those under study the 10 consumption baskets each of the separately.

### **2.2.1 Annual Inflation Rates at the “All Items” levels**

Results show that the annual Inflation rate for both the Published and those under study for each of the 10 baskets for All Items are almost the same. In addition, it was found out that in some cases, the numbers are exactly the same at the significant level of dissemination i.e. one decimal place. More details are available in attached tables, Table 3 and Table 4.

### **2.2.2 Annual for the Transport Division**

Results show that the annual Inflation rate for the transport division for the Mbarara consumption basket for both the Published and those under study are significantly different (see Table 5). This is due to a big drop in Transport Division weight for the Mbarara basket from the 12.41 parts per 1,000 to 9.74 parts per 1,000 which is a drop of 21.6% (see Table 2). This has a very strong signal to policy makers which may grossly underestimate the changes in prices in that region for the transport sector by excluding such items because they cannot be priced.

For the rest of the remaining for rest of the remaining 8 consumption baskets The annual inflation rates for Transport Divisions for both the published and those under study are almost the same. In addition it was found out that in some cases, the numbers are exactly the same at the significant level of dissemination i.e. one decimal place. More details are available in attached tables, Table 5 and Table 6.

## **2.3 CPI for All Items and for the Transport Division**

CPI for the All Items and those for the Transport Divisions for each of the 10 consumption baskets are attached as: Tables 7; Tables 8; Tables 9; and Tables 10.

### **3. CONCLUSIONS AND RECOMMENDATIONS**

#### **3.1 Summary of the Findings**

The study shows that the weights for each of the 10 consumption baskets changed. In addition, the weights within each of the consumption basket changed more especially the Transport Division weights. The Transport Division weights changed significantly in 8 out of the 10 consumption baskets. The extreme case was registered on the Mbarara basket whose transport division changed sharply.

Despite the above observed changes in weights, results show that the All Items CPI and the All Items Annual Inflation for each of the 10 consumption baskets for both the published and those under study were not much different and in some cases exactly the same at the significance level of dissemination.

However, the CPI for the Transport Division for the Mbarara basket and the corresponding annual Inflation for both the published and those under study are significantly different. This is due to a relatively very bigger expenditure on second hand vehicles by the households of Mbarara sub-region compared to other sub-regions. When the expenditure for the second hand vehicles was removed from Mbarara, due to its magnitude, it caused a big distortion in transport weight, hence its division CPI.

The CPI for the Transport Division for other consumption baskets and their corresponding annual Inflation for both the published and those under study are not significantly different.

#### **3.2 Conclusion**

The study was based on one expenditure item and there could be other items that fall under the same category. Given the increasing demand for data at disaggregated level, more especially at lower levels of local administration, the choice taken to compile the CPI leads to different results and a wrong choice may be undertaken. Removing expenditure from a sub-region because it cannot be priced, is very misleading and can result into wrong policy at the local level given distorting the household expenditure pattern and hence the CPI for that locality. Thus, the best option is to keep the expenditure where it is incurred and use a price from a different region or sub-region where it can be obtained provided that the principal of like-with like is maintained. In addition, the principle of proportional reallocation of expenditure when such products cannot be priced within a sub-region should be discouraged unless in the whole country reliable prices cannot be obtained on a regular basis.

Some countries have established regional economic blocks e.g. East African Community (EAC), Common Market for Eastern and Southern Africa (COMESA), South Africa Development Community (SADC) etc... Those regional blocks do compile the Harmonised Consumer Price Indices (HCPI) and they follow the domestic concept. In order to have meaningful sub-regional indices within a country, I would recommend the domestic concept to be restricted at the national level and the expenditure within the country be allocated to the households within the sub-region they reside. This implies that only consumption expenditures within the economy should be considered but within the economy, consumption should be assigned or allocated to the households who make the expenditures to their region or sub-region where they stay but not to the sub-regions where the expenditures are made.

Despite changes in the weights for both between and within the 10 consumption baskets, the Annual Inflation for the 10 consumption baskets at the All Items level for both the published and those under study are almost the same and in some cases exactly the same at the significant level of dissemination. The results apply also to the Transport Division except for the Mbarara basket. Those results shows the need to ensure that all prices entered for the computation of the CPI are of very high quality since price movements have a much bigger impact on the inflation to be published and disseminated compared to the weights.
