

## **ANNEX I**

### **Long-term country profile sheets**

## **Long-term country profile sheets**

The long-term country profile sheets which follow present tables and graphs providing comprehensive information about the major EFSOS outcomes. The data presented are derived from statistics, the analytical work on historical trends and the three forecast scenarios (“Baseline”, “Integration” and “Conservation”) of forest resources and forest products markets. For further information about the methodologies applied in the various analytical tools, see the descriptions in the main report above. The tables and graphs are structured by countries, which are aggregated into the three subregions: EU/EFTA, EU/EFTA “after accession”, CEEC and CIS, as well as Europe as a whole.

Such a comprehensive overview presents an efficient information base for the EFSOS target groups: governments, the private forest sector industry and non-governmental organizations as well as for the public in general. International organizations and policy processes are expected to use the information for their own conclusions and recommendations. The overview is valuable for the scientific community as it invites researchers to verify the EFSOS outcomes, based on their own knowledge. Feedbacks from country experts would be welcome to improve the information and further increase reliability.

### Forest resources, historical trends

The information provided is based on the special analysis “Historical Trends in Forest Resources in Europe”, Annex 5 (see UNECE/FAO DP ...).

For forest area, data presented, refer to Forest Available for Wood Supply (FAWS). Growing stock, increment and fellings are the volumes applicable to FAWS and are shown in m<sup>3</sup> over bark (m<sup>3</sup> o.b.), removals in m<sup>3</sup> under bark (m<sup>3</sup> u.b.).

The area of FAWS and volume of growing stock and increment are calculated as ten-year averages by linear interpolations between the data points provided by the national correspondents or taken from historical FRA publications.

Removals data are taken from the UNECE/FAO timber database and converted into fellings. The ratio between fellings and removals is taken from the TBFRA 2000 main report (ECE/TIM/SP/17), dividing removals (Table 50) by fellings (Table 47). These ratios differ significantly between countries, and in a few cases appear anomalous or unreliable.

In order to produce totals for the subregions, in particular for CEEC and CIS, missing historical data for the period of 1970 and 1980 (e.g. for countries which have emerged after the collapse of planned economies in Eastern Europe) were estimated on the basis of additional assumptions. It is assumed that forest products markets in the “new” countries have developed with similar growth rates as in the previous state. That means, for example in the case of Slovakia and Czech Republic, the average 10 year growth rates of Czechoslovakia were applied to the 1990 figures for the two “new” countries. It should be also noted that the average of 1990 in these “new” countries presents mostly the average from 1992 to 1995. Considering the drastic shrinking of production and consumption in the beginning of the 1990s, the 1990 data is thus, in these cases, lower than the real average from 1986-1995. The same approach, as described here, was also used for the historical trends of production and consumption of forest products.

### Production, net trade and consumption, historical trends

The source for production and consumption information is the UNECE/FAO Timber Database, which was analysed in a special study “Historical Trends in Forest Products Markets”, to be published in the Discussion Paper series of UNECE/FAO. Net trade is

calculated as the difference between consumption and production (by convention “+” = net exports, “-“ = net imports).

All information presents 10 year averages (1970: (1966-1975), 1980: (1976-1985), 1990: (1986-1995)). The data for 2000 is taken from the market modelling outcomes, where an average for the last five years (1996, 1997, 1998, 1999, 2000) was used as the base period for the projection scenarios.

It should be noted that there may be minor differences between the UNECE/FAO Timber Database, the current country profiles, the analytical paper mentioned above and the econometric modelling database, as the databases are constantly evolving as data are validated or improved. Because of time constraints it was not possible to reconcile the data from all sources back to UNECE/FAO Timber Database.

In case of missing historical data the average growth rates of the previous countries were used to estimate the historical developments in “new” countries (see “Forest resources, historical trends” above).

#### Forest resources, forecast scenarios

The information comes from the “Outlook for Forest Resources in Europe”, country tables. The methodology is described in more detail in a separate paper and a brief overview is given in the text of the main report above.

In some cases the roundwood removals, generated by the EFISCEN model, did not fit to the derived roundwood demand generated by the market model. In case of a “shortage” (i.e. EFISCEN removals data lower than the level of removals forecast in the trade and markets model), additional net imports of roundwood were assumed and calculated in the following tables under net trade. In most of the cases the volumes are either negligible or can be explained, as in the case of Russia (see below).

In some other cases (Austria, Denmark, Greece, Turkey, Slovenia, Slovakia, Moldova and partly Ukraine) the original EFISCEN roundwood removals are much higher than the derived roundwood demand from the trade and markets model. This is obviously caused by problems in the data transfer between the market and forest resource modelling. In these cases the secretariat has suppressed the “oversupply” by showing the derived roundwood production figure also under roundwood removals.

As a result roundwood removals and roundwood production are identical in all following tables.

It should be noted, that in all cases where adjustments have been made to the differences between roundwood removals provided by the EFISCEN model and derived roundwood demand (production) given by the market model, the growing stock and increment data have not been attuned to the forecast of roundwood removals and fellings.

The conservation scenario was not estimated partly because of limited resources, but also because it appeared less of an issue. The reason for this is that the lower level of consumption and production of forest products would lead to a derived roundwood demand lower than in “Baseline” and “Integration” scenarios. Thus the pressure on forest resources to fulfil this demand would be lower than in these two scenarios. However, the potential reduction in the area of FAWS due to higher conservation requirements and the resulting decline in the production potential of the forest were not modelled.
