Area and sub-area	Impacts Human settlements and human health					
Presentation						
Tier	2					
Indicator definition and description	Incidence of vector-borne diseases influenced by climatic conditions reported during a year. Vector-borne diseases influenced by climatic conditions include: Lyme disease (A69.2), malaria (B50- B54), West Nile virus (A92.3), yellow fever (A95), dengue(A97).					
Unit of measure	Percentage					
Coverage	Resident population					
Spatial aggregation	National territory					
Reference period	Calendar year					
Update frequency	Annual					
Base period	Not applicable

ID	Subindicator				Туре	
77 Estimated nu	umber of cases of the selected vector-borne diseas			ses	Contextual indicator	
85 Reported number of cases of the selected vector-borne disease			25	Contextual indicator		
Relevance						
Policy context and rationale Numerous climate change vulnerability assessments anticipate that rising global temperatures will increase the incidence of communicable diseases including vector-borne diseases (VBDs). Globally, vector-borne diseases account for more than 17% of all infectious diseases, causing more than 1 million deaths annually. Globalization of travel and trade, unplanned urbanization and environmental challenges such as climate change are having a significant impact on disease transmission in recent years. Some diseases, such as dengue, chikungunya, and West Nile virus, are emerging in countries where they were previously unknown. Changes in climate are likely to lengthen the transmission seasons of important vector-borne diseases and to alter their geographic range. Malaria (transmitted by Anopheles mosquitoes) is strongly influenced by climate. The Aedes mosquito vector of dengue is also highly sensitive to climate conditions, and studies suggest that						

climate change is likely to continue to increase exposure to dengue (WHO).

## 26 Incidence of climate-related vector-borne diseases

Indicator type Core indicator

	The development and survival of ticks, their animal hosts, and the bacterium that causes Lyme disease are all strongly influenced by climatic factors, especially temperature, precipitation, and humidity (CDC). Future climate change in Europe is therefore likely to facilitate the spread of Lyme borreliosis in the same way, while reducing its occurrence in areas that become hotter and drier.

Comments						
Comments	The number of reported cases may differ from number of estimated cases. The reported number can be affected by: - the completeness of reporting: the number of reported cases can be lower than the estimated cases if the percentage of health facilities reporting in a month is less than 100% - the extent of malaria diagnostice tsting - the use of private health facilities which are usually not included in reporting systems. - the indicator is estimated only where malaria transmission occurs.
