Introduction

- ① Economic variables with highly skewed distribution very usual in business survey
- ② **Influential units problems**
- ③ it a way to limit the impact of these values in estimators ?
- ④ Main issue : determination of the atypical units

⇒ **Winsorization**

- 5 Conclusion

Winsorization

- **Winsorization** : transformation of the a variable of interest Y into another Y^* defined as :

$$Y^* = \begin{cases} Y & \text{if } Y \leq K_h \\ \frac{n_h}{N_h}Y + (1 - \frac{n_h}{N_h})K_h & \text{if } Y > K_h \end{cases}$$

- We have to fix a value for K_h : this is where different approaches come.

- 5 Conclusion

Kokic and Bell approach

We suppose that we have a stratified sample and note h the quantity depending of the strata h .

$$K_h = -\frac{B}{\frac{N_h}{n_h} - 1} + \mu_h$$

- ① Using this K_h , the winsorized estimator extend the HT estimator.
- ② Winsorized estimator biased but has the smallest error in estimator the total of Y on average of all possible samples.
- ③ B is the bias of the minimum winsorized estimator, n_h is the number of units sampled in the stratum h , N_h is the size of population in stratum h and μ_h is the expectation of Y in the stratum h .

How to calculate the bias B ?

The bias B is calculated as a zero of the function:

$$F(B) = -B[1 + \sum_h n_h E_h(J_h^*)] - \sum_h n_h E_h(Y_h^* J_h^*)$$

- E_h is the expectation in the stratum h
- $Y_h^* = (\frac{N_h}{n_h} - 1)(Y_h - \mu_h)$
- $J_h^* = 1$ if and only if $Y_h \geq K_h$

The function can be rewritten as a function of $L = -B$ and computed as a piecewise affine function.

Clark method

The Clark method works not only for stratified samples, we need auxiliaries variables. It's a generalization of Kokic and Bell method.

- ① Hypothesis: in each stratum, $Y_h = \mu_h + \epsilon_h$ (same as Kokic and Bell)
- ② $K_h = -\frac{B}{\frac{N_h}{n_h} - 1} + \mu_h^*$ with $\mu_h^* = E[\min(Y, K_h)]$, difficult to calculate so we need to estimate it by $\hat{\mu}_h$
- ③ Find the zero of the function $L - E[\sum_{i \in s} \max(\hat{D}_i - L, 0)]$ with $\hat{D}_i = (Y_i - \hat{\mu}_i)(\omega_i - 1)$, ω_i being the weight of unit i .

Connecting the two approaches

- The two functions used in the two methods can be connected with some hypothesis, so it seems to be the same method...
- ... But there is a main difference : calculation of μ_h , Kokic and Bell propose to use an independant survey/a previous edition of the survey to compute a value that estimate μ_h whereas Clark proposes to find it using a regression.
- Is there a big difference between the two ways of calculate μ_h ?

Table of Contents

- 1 Introduction
- 2 Winsorization

- 4 Application to real data : a French survey**
- 5 Conclusion

Application to real data : a French survey, ESA-EAP

- The ESANE system makes it possible to produce structural business statistics in France. This is done through an annual survey, ESA-EAP, of approximately 160,000 companies.
- We used the data of the 2020 survey to compare the impact of winsorization with the two methods : Kokic and Bell (KB) and Clark.
- In the survey, we make a difference between the companies with only one legal unit (called independant unit) and those with several legal units (called profiled companies).

Results

	KB	Clark - independant data	Clark - sample	Clark - corr. factor
Ind. units	283	35	1616	1448
Other	158	28	459	340
Total	441	63	2075	1788

- $\times 7$ using KB instead of Clark - independant data (preconised solution)
- but $\times 4$ using Clark with other ways of calculate μ_h

Table of Contents

- 1 Introduction
- 2 Winsorization
- 3 The two methods : Kokic and Bell vs Clark
- 4 Application to real data : a French survey
- 5 Conclusion**

Conclusion

- ❶ The two methods can be reunited by rewriting the functions we have to use...
- ❷ ... but one main difference : estimation of μ_h
- ❸ In real data, we see that the method leads to very different results.
- ❹ Which method is the best ? Simulations to do to try to see which method has the least RMSE.

Thank you!
