# Potential of using Earth observation data for producing UNECE air quality indicators

Dr. Anu-Maija Sundström,  
*Earth Observation Research,  
Space and Earth Observation Centre,  
Finnish Meteorological Institute*

26.4.2023

# Introduction

- Satellites have provided observations on multiple air-quality relevant parameters for several decades.
  - Trace gases, aerosols
  - Supporting data e.g. fire observations
- In recent years the development of satellite observations has been significant (instrumentation, spatial resolution, methods)
- It is likely that with satellites' improved spatial and temporal resolution, the use of satellite observations to support air quality monitoring will increase in the future.

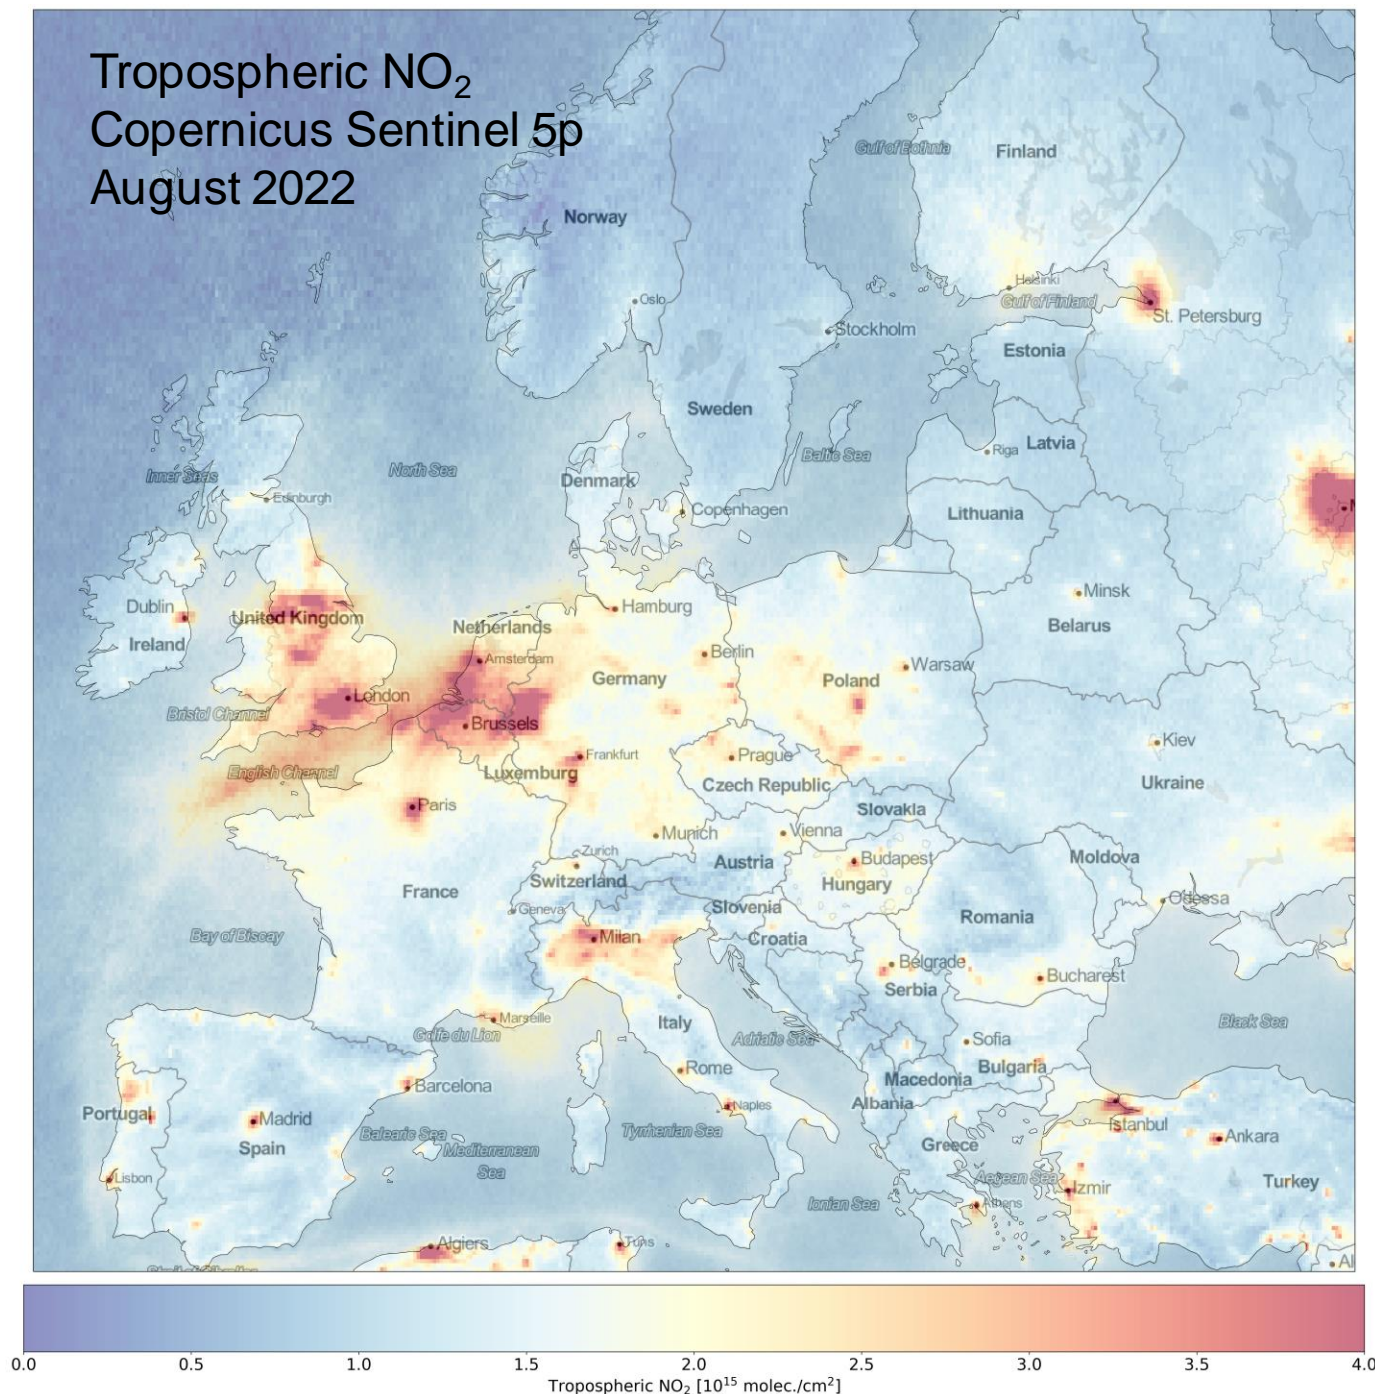

- Advantages of satellite observations

- Filling gaps between in situ stations and increase understanding of regional-scale air quality variation.
- Potential to detect emission hot spots.
- Observations over area where in situ measurements are completely missing.
- Long global timeseries available (+15yrs)
- Data from the largest providers (EU Copernicus, NASA, ESA, EUMETSAT etc.) are **free** and **open** for everyone.

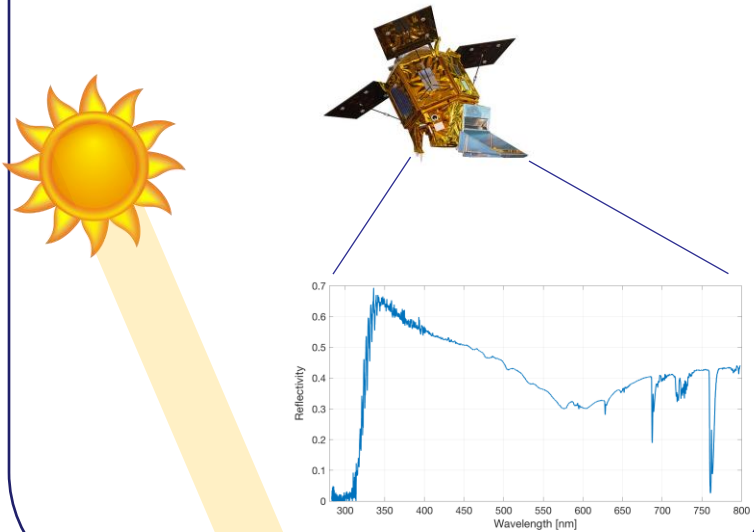

- Challenges of satellite observations

- Interpretation and handling datasets require expertise
- With new instruments data amounts are large.
- Cloudiness, lack of solar light (winter, night) can prevent observations -> uneven sampling.

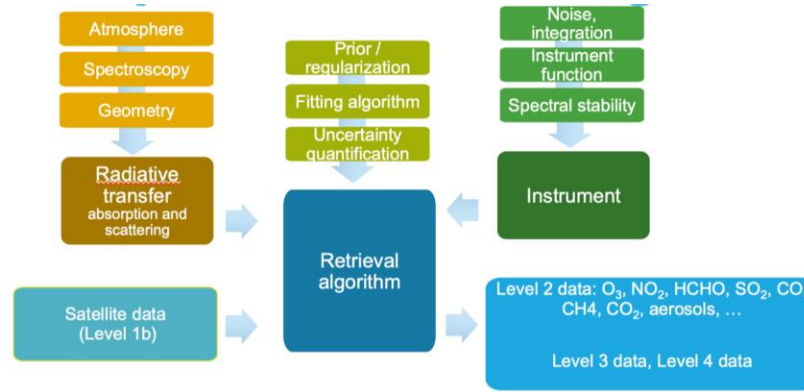

# From radiation measurements to atmospheric observations

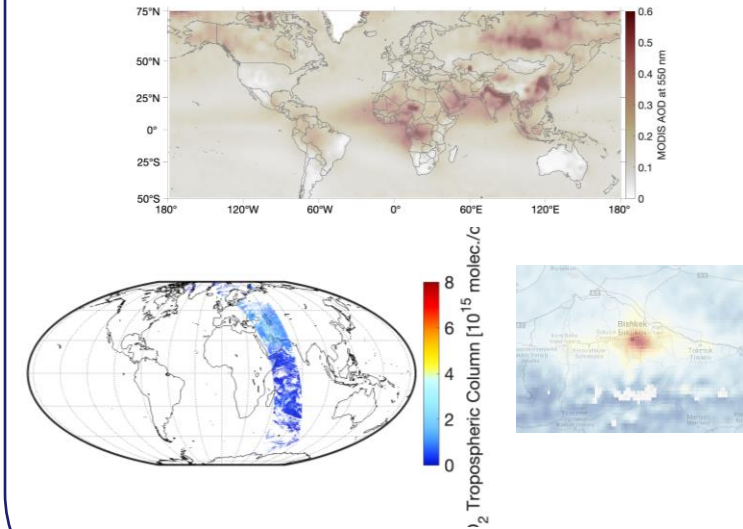

## Satellite measurement of reflected solar radiation or emitted thermal radiation

## Retrieval algorithm

## Atmospheric observations

# Interpretation of satellite observations

- Satellites measure concentrations or other quantities in an **atmospheric column**.
  - This is the essential difference as compared to in situ measurements.
  - Satellite measurements are not directly comparable to in situ measurements, also units are different.
- How representative column measurements are to pollution at surface depends on many factors
  - Which parameter is considered (trace gases, aerosols)
  - Meteorology
  - Strength of emission source
  - Transported pollution
  - Vertical sensitivity of satellite instrument
  - etc.

Sources of pollutants only close to surface, no long range transport →

- changes at surface likely also visible in the total column concentration.

Pollutants at surface and at upper level transported pollution →

- Satellites measure the total column
- In situ measurements see only the pollution close to the surface

# Satellite observations for air quality monitoring

**NO<sub>2</sub>**

**NO<sub>2</sub> Tropospheric column density**  
**Instruments:** TROPOMI (S5p), OMI (Aura), GOME-2 (Metop -A,B,C, )

**Aerosols**

**Aerosol Optical Depth (AOD)**  
**Instruments:** SLSTR (S3), MODIS (Aqua, Terra), VIIRS (S. NPP, NOAA-20)

**SO<sub>2</sub>**

**SO<sub>2</sub> total column density**  
**Instruments:** TROPOMI, OMI, GOME-2, OMPS (S. NPP, NOAA-20)

**CO**

**SO<sub>2</sub> total column density**  
**Instruments:** TROPOMI, IASI (Metop A,B,C)

(Satellite instrument list not complete)

- Other potentially useful satellite data: active fires, RGB images, etc.

# Air Quality in Bishkek

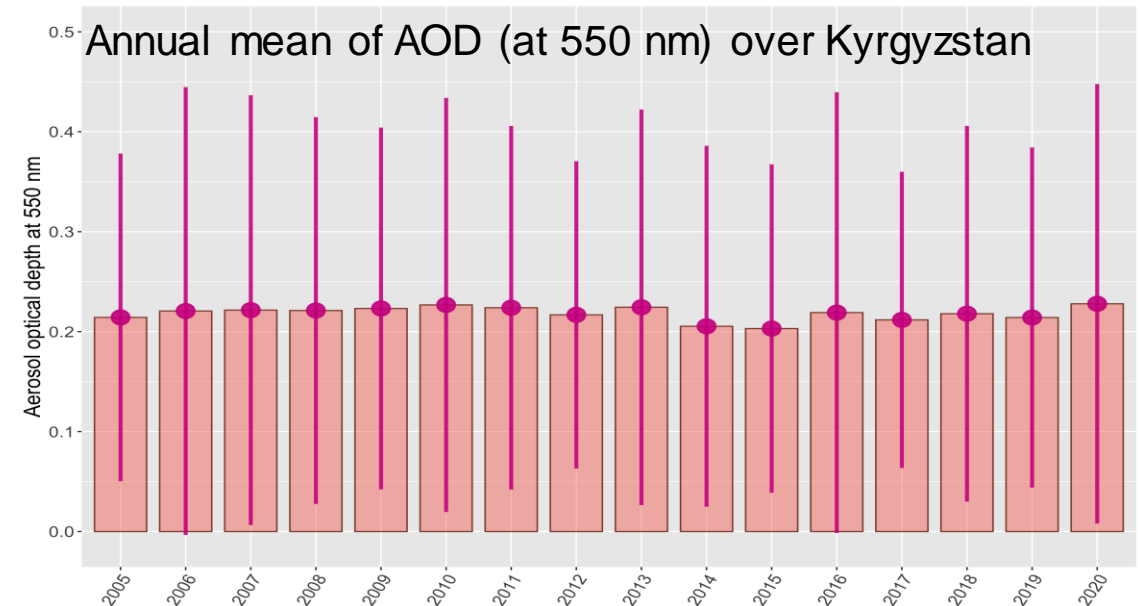

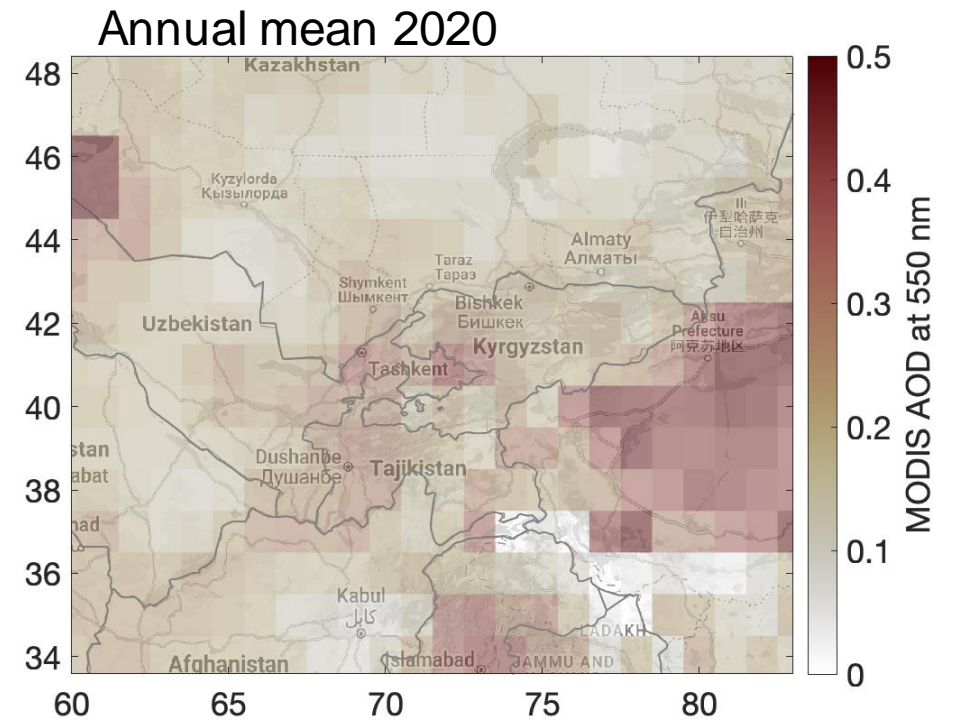

An Example on the Use of Satellite Data to Support  
Air Quality Assessment

- The first scientific assessment of key emission sources impacting the air quality in the Bishkek
- Analysis was carried out using KyrgyzHydromet and US Embassy Air Quality Stations, available air quality sensor data and satellite observations.
- Analysed satellite parameters included:
  - Tropospheric NO<sub>2</sub>,
  - aerosol optical depth
  - total column SO<sub>2</sub>
- Report available at:  
<https://wedocs.unep.org/handle/20.500.11822/41090>  
(English, Kyrgyz, Russian)

# Aerosol Optical Depth (AOD)

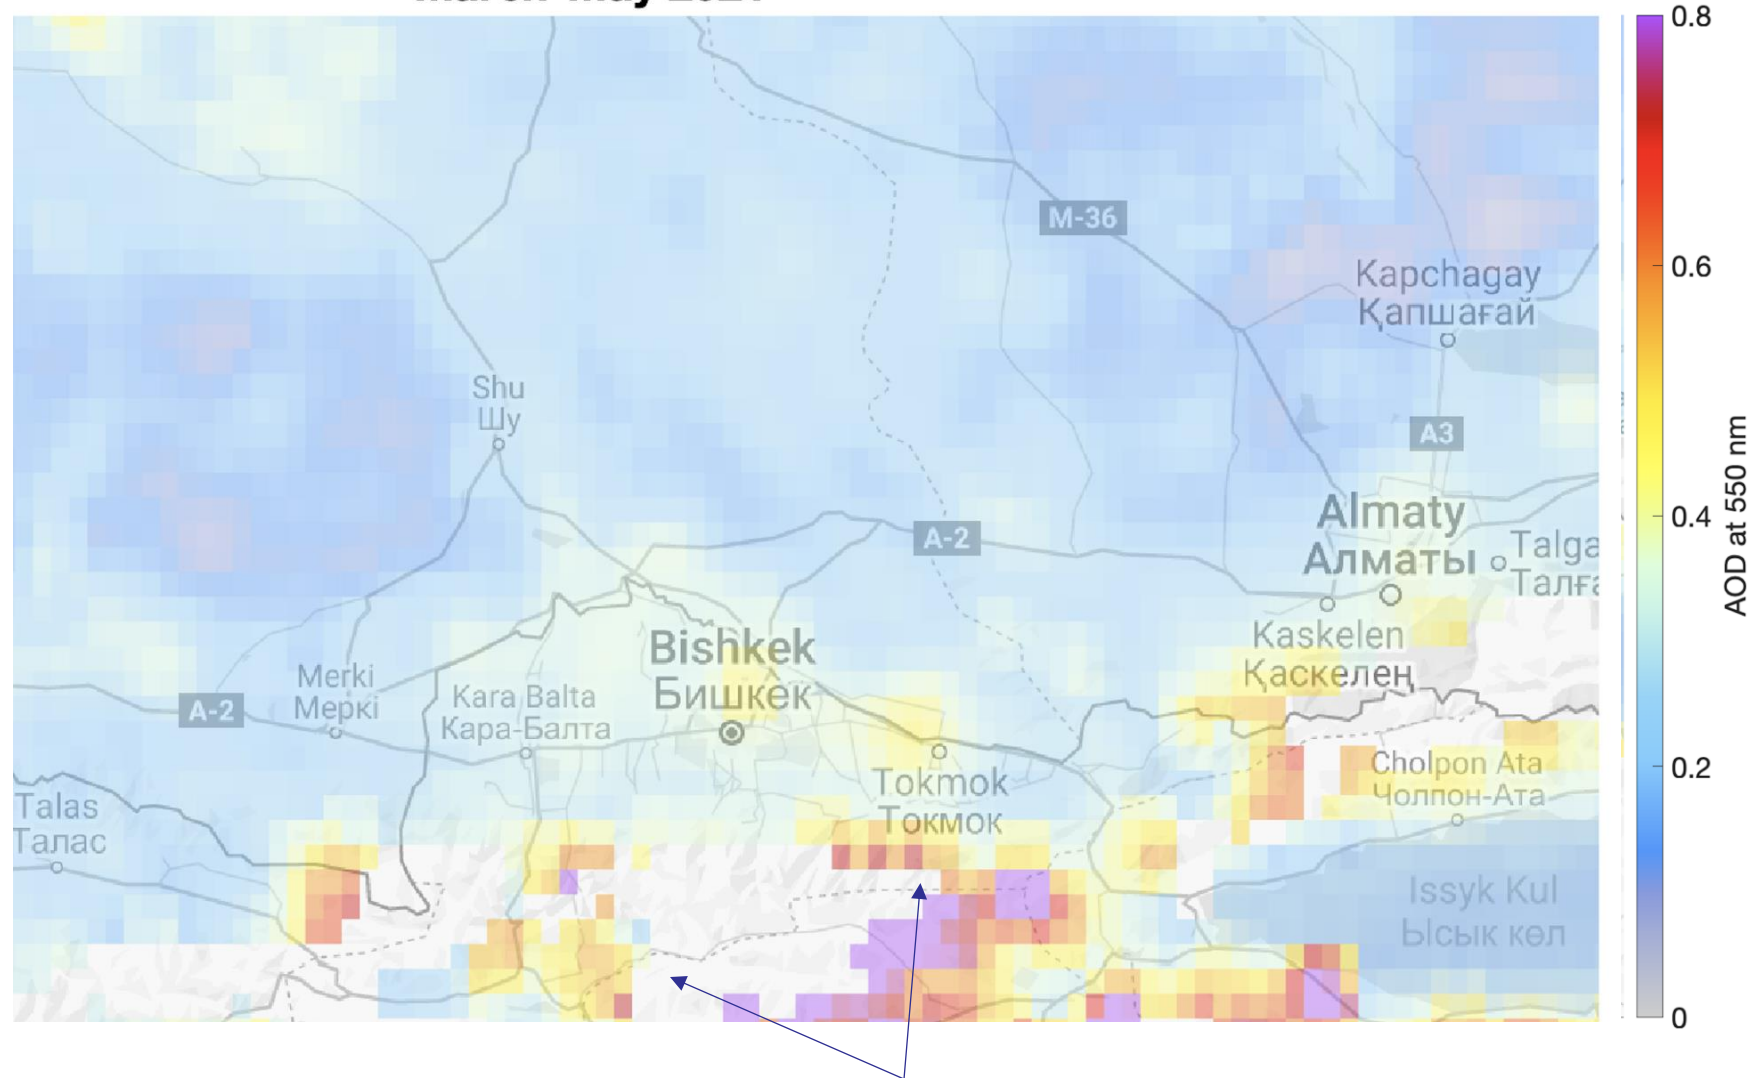

- AOD is the primary parameter from satellites to assess the amount of aerosols in an atmospheric column
  - AOD is related to the aerosol number concentration
- AOD correlates to some extent with PM10 and PM2.5, but there are essential differences
  - AOD is sensitive to all sizes of optically active aerosols, AOD is over total column, etc.
  - Estimating PMs from AOD is very challenging, recently machine learning –based methods have been developed
- Over Kyrgyzstan AOD remains at low to moderate level, no trend in the 15 yr annual means
  - Especially during spring time satellites indicate dust transport from Taklamakan desert.

# Aerosol Optical Depth (AOD)

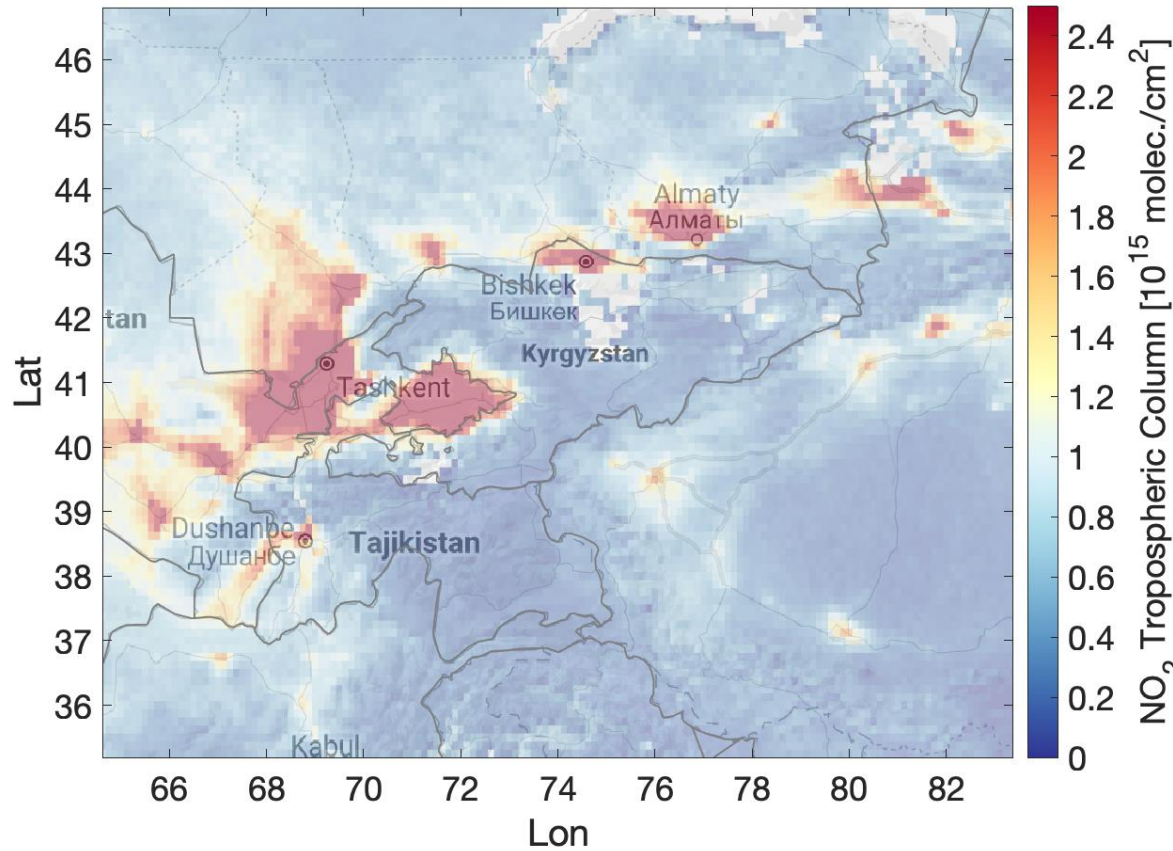

March-May 2021

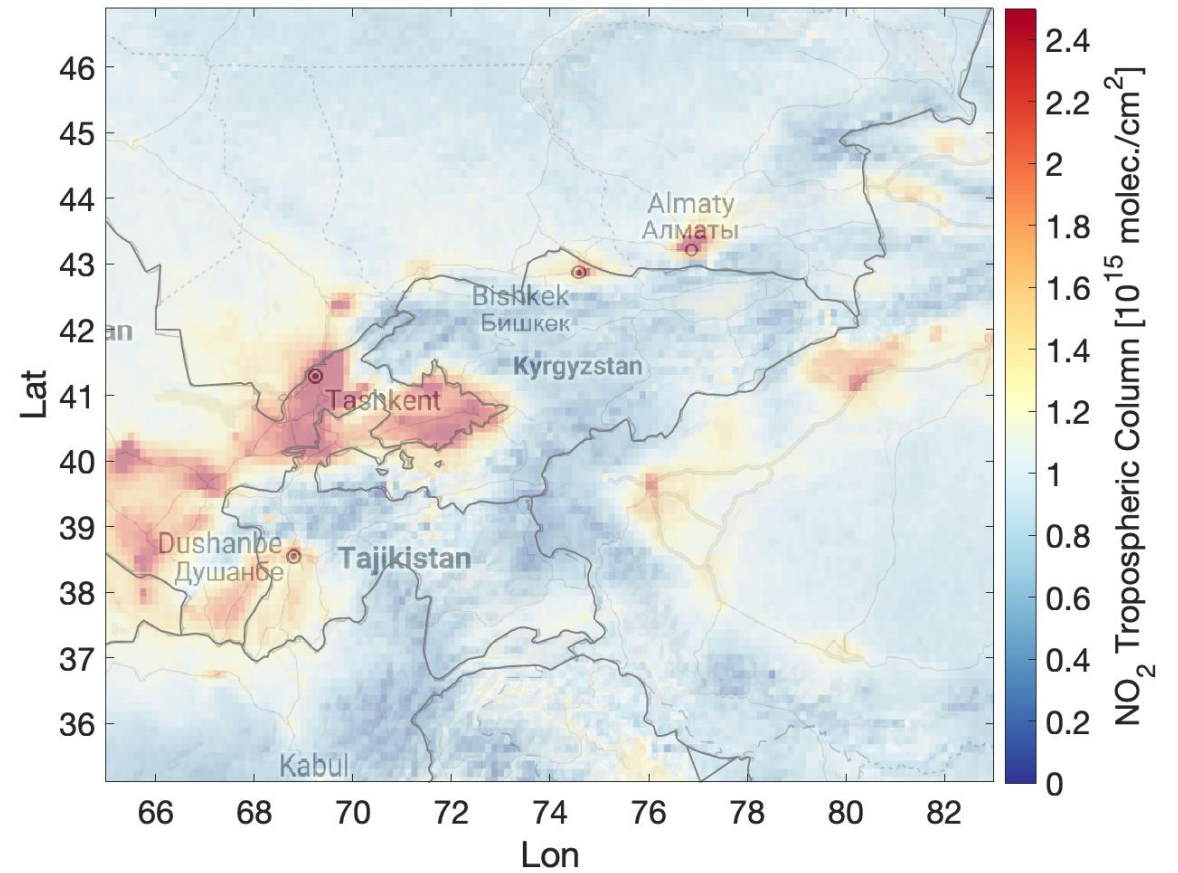

- Challenges over mountaneous area
- part of elevated singnal true and related to dust transport

# Satellite observations of nitrogen dioxide Tropospheric column ( $\text{NO}_2$ )

TROPOMI  $\text{NO}_2$  February 2020

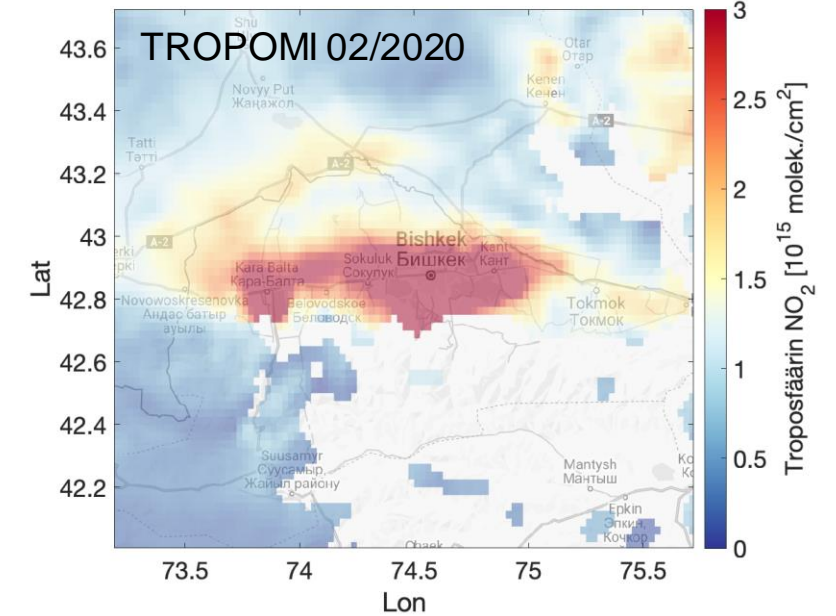

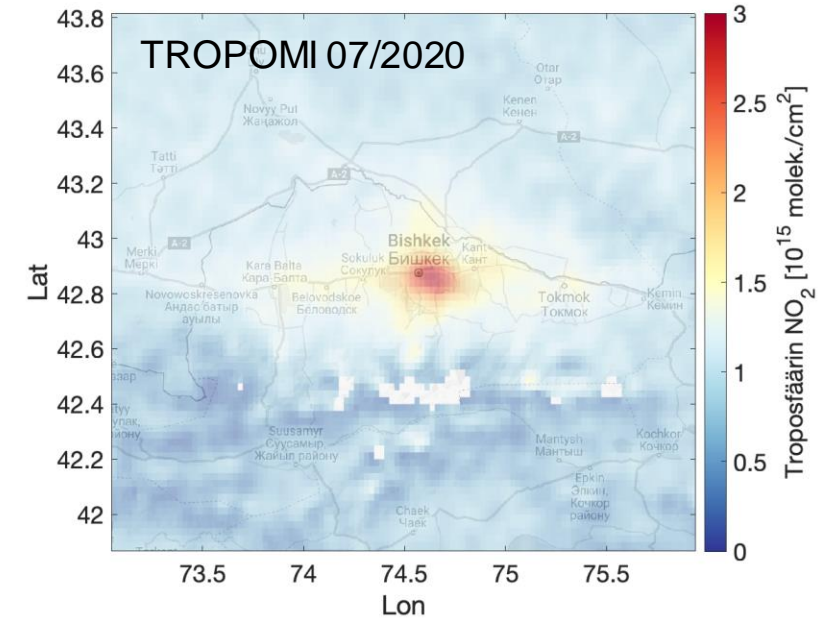

TROPOMI  $\text{NO}_2$  July 2020

# Annual mean of Tropospheric NO<sub>2</sub> from the OMI instrument for Kyrgyzstan

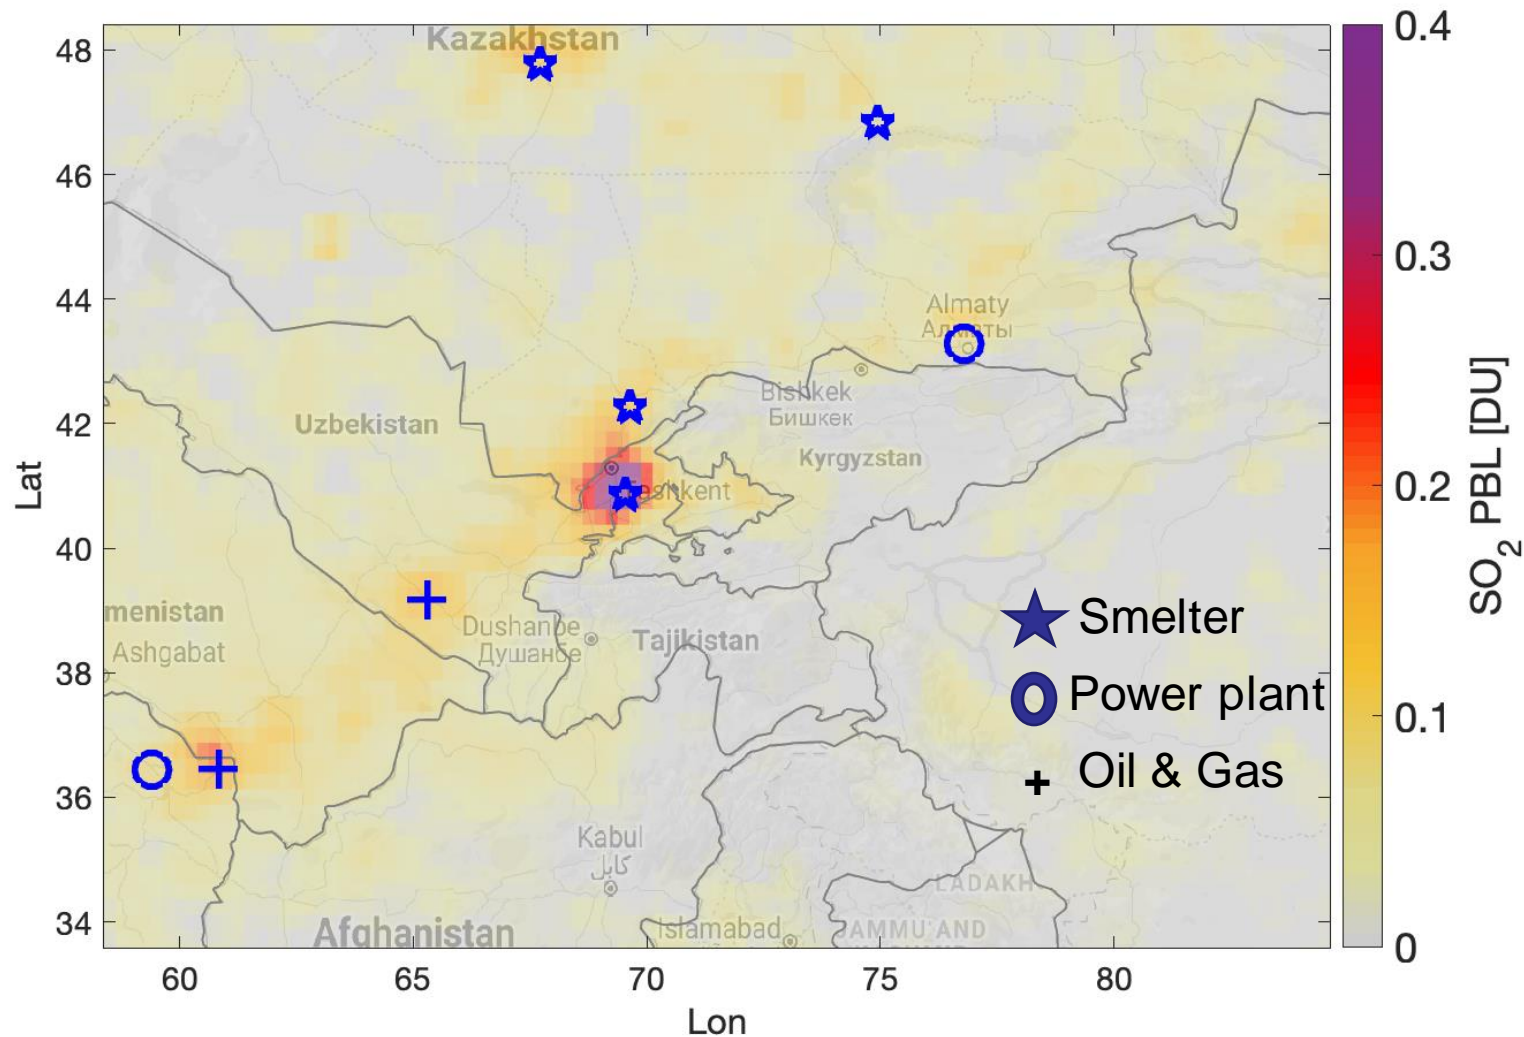

## Bishkek

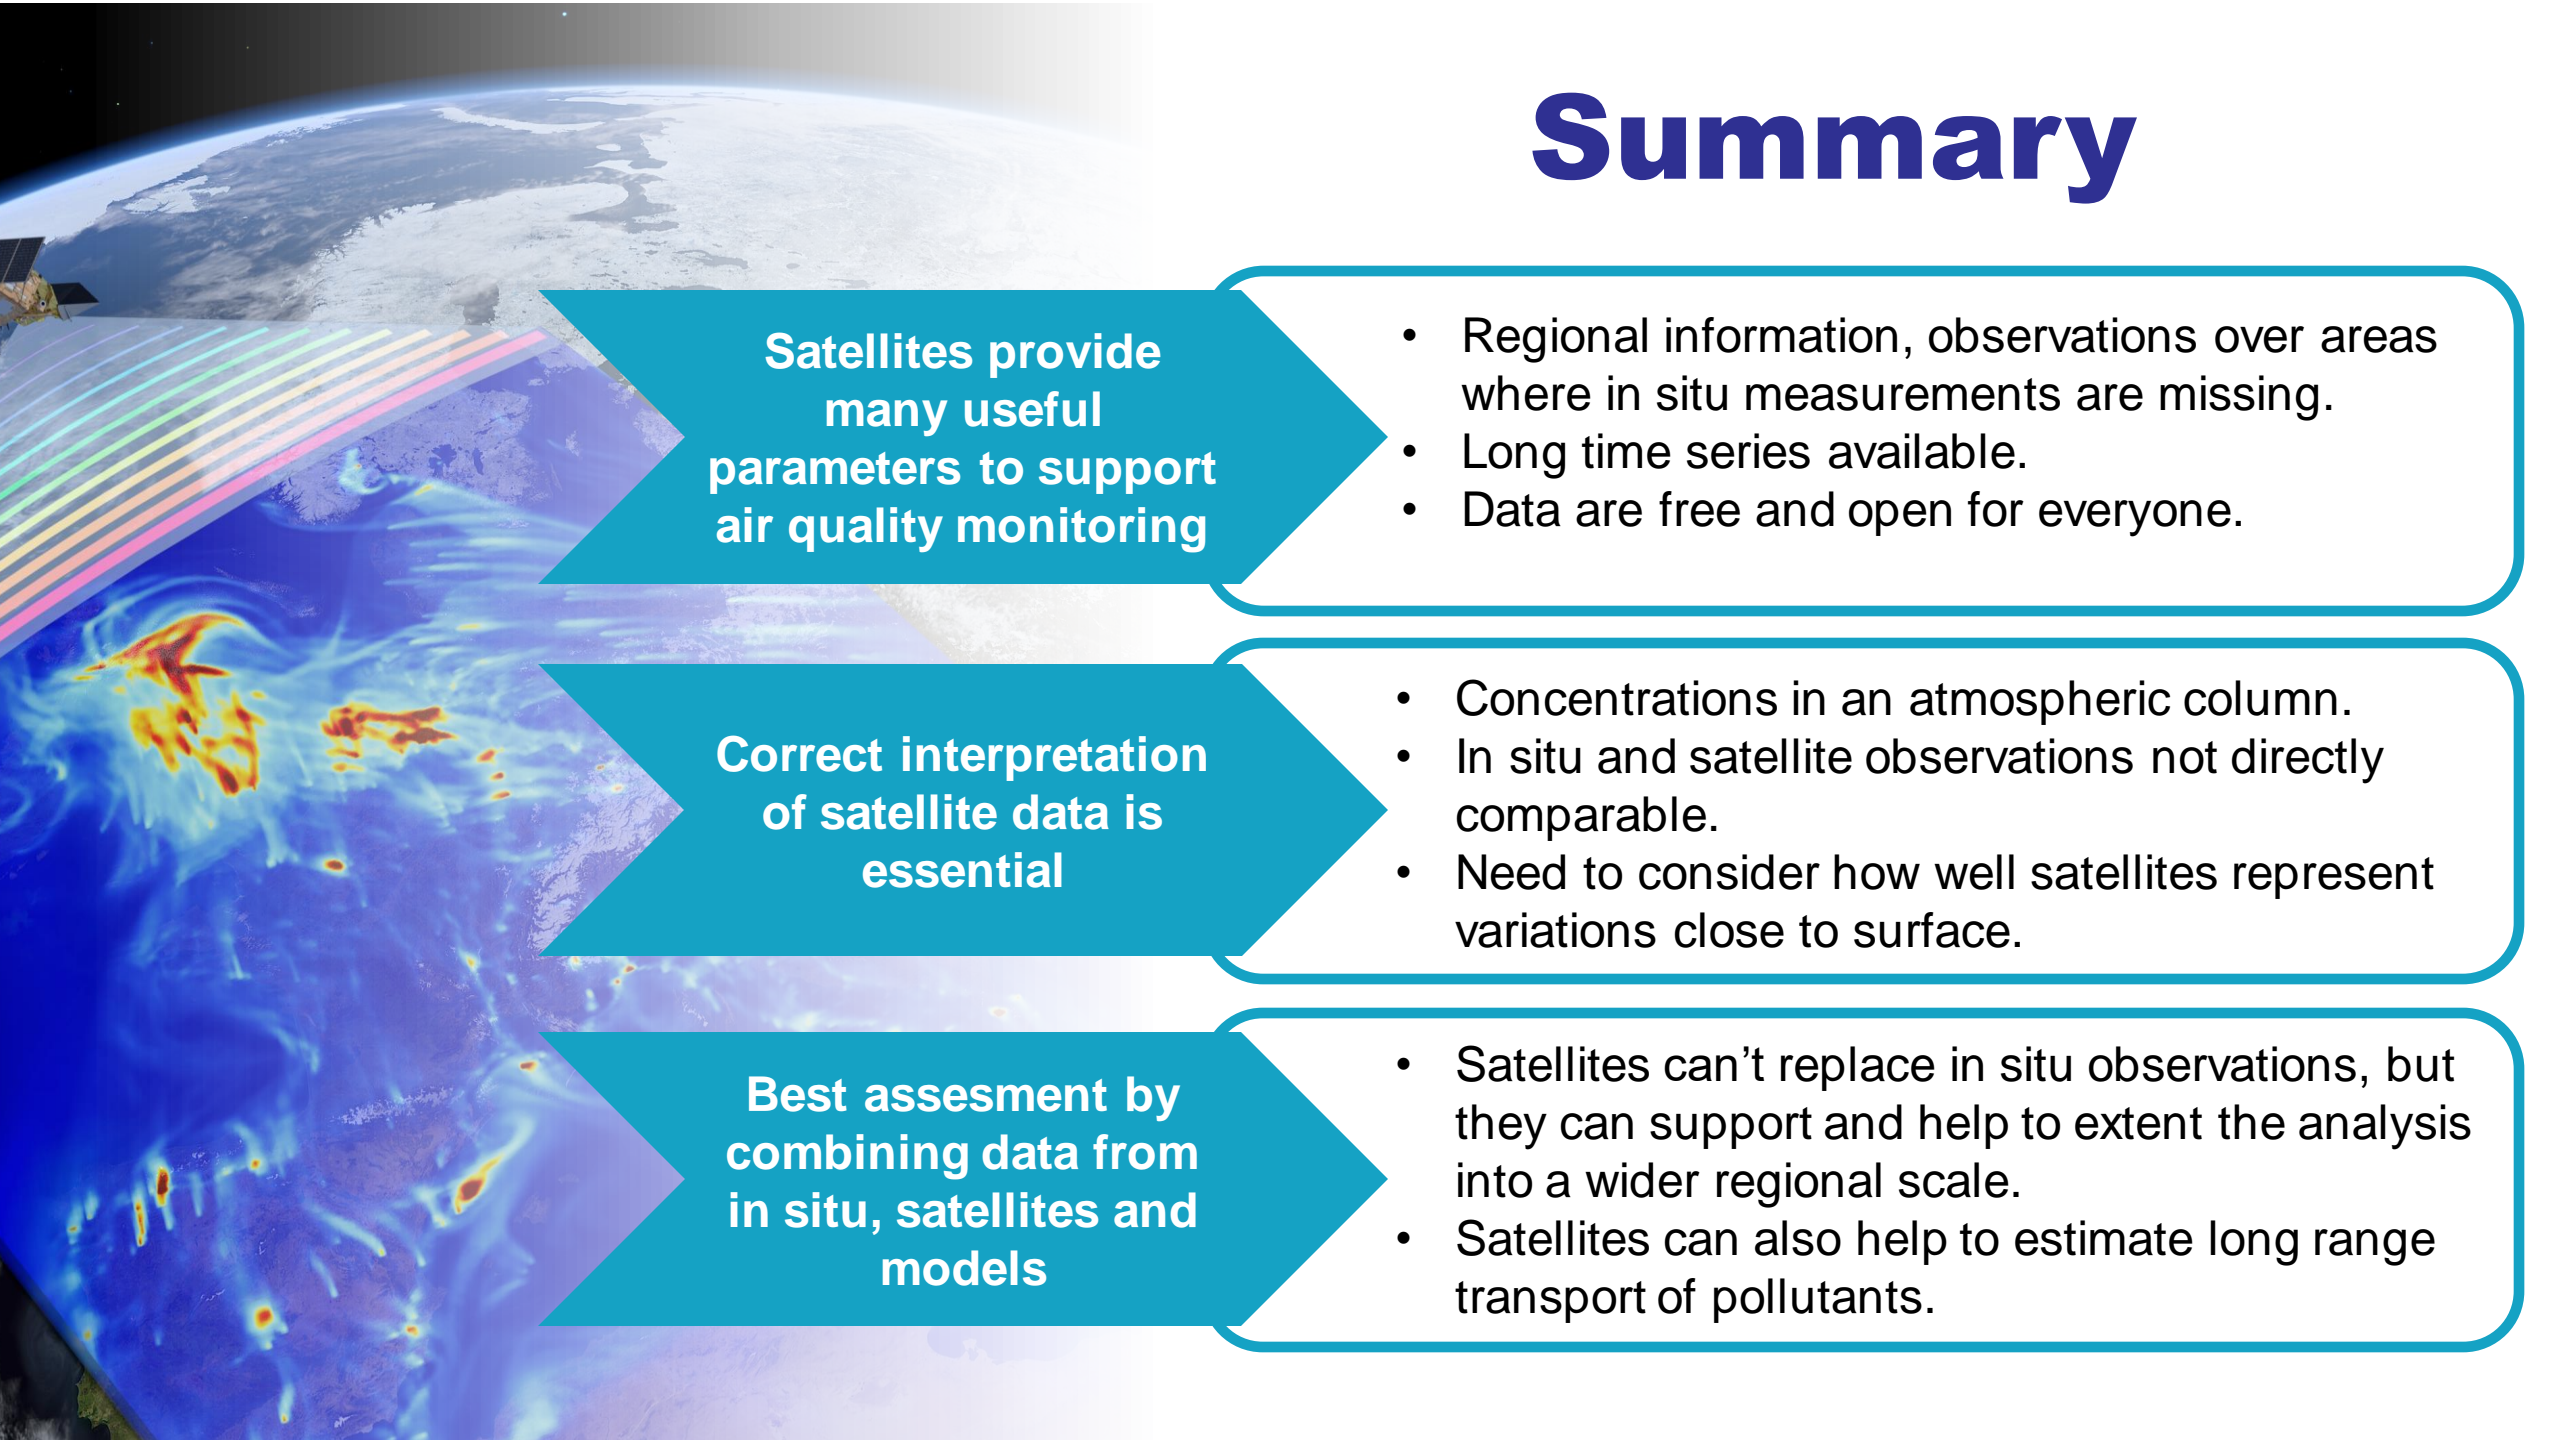

# Satellite-based total column of sulphur dioxide (SO<sub>2</sub>)

2019 Annual Mean (OMI instrument)

- In situ observations in Bishkek showed high SO<sub>2</sub> concentrations
- From satellite data no major emission sources could be identified over Kyrgyzstan, and total column SO<sub>2</sub> remained low
  - Detecting SO<sub>2</sub> from satellites is challenging.
  - Anthropogenic source needs to be strong point source to be “visible” for satellites.
- The most likely explanation for the difference is that in Bishkek SO<sub>2</sub> is originating from multiple smaller sources that “averages out” in satellite pixels (single pixel several square km).

# Summary

**Satellites provide many useful parameters to support air quality monitoring**

- Regional information, observations over areas where in situ measurements are missing.
- Long time series available.
- Data are free and open for everyone.

**Correct interpretation of satellite data is essential**

- Concentrations in an atmospheric column.
- In situ and satellite observations not directly comparable.
- Need to consider how well satellites represent variations close to surface.

**Best assesment by combining data from in situ, satellites and models**

- Satellites can't replace in situ observations, but they can support and help to extent the analysis into a wider regional scale.
- Satellites can also help to estimate long range transport of pollutants.
